Much of the time, we're really debating because we want to prove we're right and our opponent is wrong. Our interest is not in getting to the truth. We don't even consider the possibility that our opponent might be correct or that we could learn something from them. As decades of psychological research indicate, our brains are always out to save energy, and part of that is that we prefer not to change our minds about anything. It's much easier to cling to our existing beliefs through whatever means possible and ignore anything that challenges them. Bad arguments enable us to engage in what looks like a debate but doesn't pose any risk of forcing us to question what we stand for.

We debate for other reasons, too. Sometimes we're out to entertain ourselves. Or we want to prove we're smarter than someone else. Or we're secretly addicted to the shot of adrenaline we get from picking a fight. And that's what we're doing—fighting, not arguing. In these cases, it's no surprise that shoddy tactics like using straw man or hollow man arguments emerge.

It's never fun to admit we're wrong about anything or to have to change our minds. But it is essential if we want to get smarter and see the world as it is, not as we want it to be. Any time we engage in debate, we need to be honest about our intentions. What are we trying to achieve? Are we open to changing our minds? Are we listening to our opponent? Only when we're out to have a balanced discussion with the possibility of changing our minds can a debate be productive, avoiding the use of logical fallacies.

Bad arguments are harmful to everyone involved in a debate. They don't get us anywhere because we're not tackling an opponent's actual viewpoint. This means we have no hope of convincing them. Worse, this sort of underhand tactic is likely to make an opponent feel frustrated and annoyed by the deliberate misrepresentation of their beliefs. They're forced to listen to a refutation of something they don't even believe in the first place, which insults their intelligence. Feeling attacked like this only makes them hold on tighter to their actual belief. It may even make them less willing to engage in any sort of debate in the future.

And if you're a chronic constructor of bad arguments, as many of us are, it leads people to avoid challenging you or starting discussions. Which means you don't get to learn from them or have your views questioned. In formal situations, using bad arguments makes it look like you don't really have a strong point in the first place.

How to avoid using bad arguments

If you want to have useful, productive debates, it's vital to avoid using bad arguments.

The first thing we need to do to avoid constructing bad arguments is to accept it's something we're all susceptible to. It's easy to look at a logical fallacy and think of all the people we know who use it. It's much harder to recognize it in ourselves. We don't always realize when the point we're making isn't that strong.

Bad arguments are almost unavoidable if we haven't taken the time to research both sides of the debate. Sometimes the map is not the territory—that is, our perception of an opinion is not that opinion. The most useful thing we can do is attempt to see the territory. That brings us to steelman arguments and the ideological Turing test.

Steel man arguments

The most powerful way to avoid using bad arguments and to discourage their use by others is to follow the principle of charity and to argue against the strongest and most persuasive version of their grounds. In this case, we suspend disbelief and ignore our own opinions for long enough to understand where they're coming from. We recognize the good sides of their case and play to its strengths. Ask questions to clarify anything you don't understand. Be curious about the other person's perspective. You might not change their mind, but you will at least learn something and hopefully reduce any conflict in the process.

"It is better to debate a question without settling it than to settle a question without debating it."

— Joseph Joubert

In Intuition Pumps and Other Tools for Thinking, the philosopher Daniel Dennett offers some general guidelines for using the principle of charity, formulated by social psychologist and game theorist Anatol Rapoport:

1. *You should attempt to re-express your target's position so clearly, vividly, and fairly that your target says, "Thanks, I wish I'd thought of putting it that way."*
2. *You should list any points of agreement (especially if they are not matters of general or widespread agreement).*
3. *You should mention anything you have learned from your target.*
4. *Only then are you permitted to say so much as a word of rebuttal or criticism.*

An argument that is the strongest version of an opponent's viewpoint is known as a steel man. It's purposefully constructed to be as difficult as possible to attack. The idea is that we can only say we've won a debate when we've fought with a steel man, not a straw one. Seeing as we're biased towards tackling weaker versions of an argument, often without realizing it, this lets us err on the side of caution.

As challenging as this might be, it serves a bigger picture purpose. Steel man arguments help us understand a new perspective, however ludicrous it might be in our eyes, so we're better positioned to succeed and connect better in the future. It shows a challenger we are empathetic and willing to listen, regardless of personal opinion. The point is to see the strengths, not the weaknesses. If we're open-minded, not combative, we can learn a lot.

“He who knows only his side of the case knows little of that.”

— John Stuart Mill

An exercise in steel manning, the ideological Turing test, proposes that we cannot say we understand an opponent's position unless we would be able to argue in favor of it so well that an observer would not be able to tell which opinion we actually hold. In other words, we shouldn't hold opinions we can't argue against. The ideological Turing test is a great thought experiment to establish whether you understand where an opponent is coming from.

Although we don't have the option to do this for every single thing we disagree with, when a debate is extremely important to us, the ideological Turing test can be a helpful tool for ensuring we're fully prepared. Even if we can't use it all the time, it can serve us well in high-stakes situations.

How to handle other people using bad arguments

“You could not fence with an antagonist who met rapier thrust with blow of battle axe.”

— L.M. Montgomery

Let's say you're in the middle of a debate with someone with a different opinion than yours. You're responding to the steel man version of their explanation, staying calm and measured. But what do you do if your opponent starts using bad arguments against you? What if they're not listening to you?

The first thing you can do when someone uses a bad argument against you is the simplest: point it out. Explain what they're doing and why it isn't helpful. There's not much point in just telling them they're using a straw man argument or any other type of logical fallacy. If they're not familiar with the concept, it may just seem like alienating jargon. There's also not much point in using it as a “gotcha!” point which will likewise foster more tensions. It's best to define the concept, then reiterate your actual beliefs and how they differ from the bad argument they're arguing against.

1. Edward Damer writes in Attacking Faulty Reasoning, “It is not always possible to know whether an opponent has deliberately distorted your argument or has simply failed to understand or interpret it in the way that you intended. For this reason, it might be helpful to recapitulate the basic outline . . . or [ask] your opponent to summarize it for you.”

If this doesn't work, you can continue to repeat your original point and make no attempt to defend the bad argument. Should your opponent prove unwilling to recognize their use of a bad argument (and you're 100% certain that's what they're doing), it's worth considering if there is any point in continuing the debate. The reality is that most of the debates we have are not rationally thought out; they're emotionally driven. This is even more pertinent when we're arguing with people we have a complex relationship with. Sometimes, it's better to walk away.

Conclusion

The bad arguments discussed here are incredibly common logical fallacies in debates. We often use them without realizing it or experience them without recognizing it. But these types of debates are unproductive and unlikely to help anyone learn. If we want our arguments to create buy-in and not animosity, we need to avoid making bad ones.

148. Descriptions Aren't Prescriptions

When we look at a representation of reality, we can choose to either see it as descriptive, meaning it tells us what the world is currently like, or as prescriptive, meaning it tells us how the world should be. Descriptions teach us, but they also give us room to innovate. Prescriptions can get us stuck. One place this tension shows up is in language.

In one chapter of The Utopia of Rules: On Technology, Stupidity, and the Secret Joys of Bureaucracy, David Graeber describes his experience of learning Malagasy, the national language of Madagascar. While the language's writing system came about in the fifteenth century, it wasn't until the early nineteenth century that missionaries documented the rules of Malagasy grammar for the purpose of translating scripture.

Of course, the "rules" of Malagasy the missionaries recorded weren't rules at all. They were reflections of how people spoke at that point in time, as far as outside observers could tell. Languages don't usually come into existence when someone invents the rules for them. Instead, languages evolve and change over time as speakers make modifications or respond to new needs.

However, those early nineteenth-century records remained in place as the supposed "official" version of Malagasy. Children learned the old form of grammar in school, even as they spoke a somewhat different version of the language at home. For Graeber, learning to speak the version of Malagasy people actually understood in conversation was a challenge. Native speakers he hired would instruct him on the nineteenth-century grammatical principles, then turn and speak to each other in a whole other fashion. When asked why they couldn't teach him the version of the language they spoke, Graeber's Malagasy teachers responded that they were just using slang. Asked why no one seemed to speak the official version, they said people were too lazy. Graeber writes, "Clearly the problem was that the entire population had failed to memorize their lessons properly. But what they were actually denying was the legitimacy of collective creativity, the free play of the system. " While the official rules stayed the same over the decades, the language itself kept evolving. People assumed the fault of not speaking "proper" Malagasy lay with them, not with the outdated dictionary and grammar. They confused a description for a prescription. He writes:

It never seems to occur to anyone—until you point it out—that had the missionaries come and written their books two hundred years later, current usages would be considered the correct ones, and anyone speaking as they had two hundred years ago would themselves be assumed to be in error.

Graeber sees the same phenomenon playing out in other languages for which grammars and dictionaries only came into existence a century or two ago. Often, such languages were mostly spoken and, like Malagasy, no one made formal records until the need arose for people from elsewhere to make translations. Instead of treating those records as descriptive and outdated, those teaching the language treat them as prescriptive—despite knowing they're not practical for everyday use.

Why don't people talk "proper"?

So why can't people just speak a language per the official rules? If someone has gone to all the effort of identifying and recording the rules and people received instruction on them in school, why not follow them? Why keep changing things up?

If languages didn't evolve, it would make life a lot easier for historians looking at texts from the past. It would also simplify matters for people learning the language, for those coming from different areas, and even for speakers across generations. Yet all languages change all the time.

Graeber suggests the reason for this is because people like to play. We find it dull to speak according to the official rules of our language. We seek out novelty in our everyday lives

and do whatever it takes to avoid boredom. Even if each person only plays a little bit once in a while, the results compound. Graeber explains that *“this playing around will have cumulative effects.”*

Languages still need conventions so people can understand each other. The higher the similarity between the versions of a language different people speak, the more they can communicate. At the same time, they cannot remain rigid. Trying to follow an unyielding set of strict rules will inevitably curtail the usefulness of a language and prevent it from developing in interesting and necessary ways. Languages need a balance: enough guidance to help everyone understand each other and provide an entry point for learners, and enough flexibility to keep updating the rules as actual usage changes.

As a result, languages call into question our idea of freedom: *“It’s worth thinking about language for a moment, because one thing it reveals, probably better than any other example, is that there is a basic paradox in our very idea of freedom. On the one hand, rules are by their nature constraining. Speech codes, rules of etiquette, and grammatical rules, all have the effect of limiting what we can and cannot say.”* On the other hand, no rules whatsoever mean no one can understand each other.

Languages need frameworks, but no amount of grammar classes or official dictionaries will prevent people from playing and having fun with their speech.

The dictionary is not the language

“The map is not the territory” means that any representation of reality has to be a simplification that may contain errors, become outdated, or reflect biases. Maps remove details that aren’t necessary for their intended use. Representations of complex systems may show expected behavior or ideal behavior. For example, the London Underground map doesn’t reflect the distances between stations because this information isn’t important to most commuters. If a map represented its territory without reducing anything, it would be identical to the territory and therefore would be useless. In fact, the simplest maps can be the most useful because they’re the easiest to understand and remember.

Sometimes maps are descriptive, and sometimes they’re prescriptive; often they’re a bit of both. We run into problems when we confuse one type for another and try to navigate an idealized territory or make the real territory fit an idealized image.

A language’s grammar and dictionary are a sort of map. They take a complex system—a language spoken by what could be tens of millions of people—and aim to represent it with something which is, by comparison, simple. The official rules are not the language itself, but they provide guidance for navigating it. Much like a map of a city needs periodic updates as parts are torn down, built up, renamed, destroyed, added, and so on, the official rules need updating as the language changes. Trying to learn Malagasy using grammar rules written two hundred years ago is like trying to navigate Antananarivo using a street map made two hundred years ago.

A map of a complex system, like a language, is meant to help us find our way by giving us a sense of how things looked at one point in time—it’s usually descriptive. It doesn’t necessarily tell us how that system should look, and we may run into problems if we try to make it conform to the map, ignoring the system’s own adaptive properties. Even if the cartographer never intended this, we can end up treating a map as a prescription. We try to make reality conform to the map. This is what occurs with languages. Graeber calls this the “grammar-book effect”:

People do not invent languages by writing grammars, they write grammars—at least, the first grammars to be written for any given language—by observing the tacit, largely unconscious rules that people seem to be employing when they speak. Yet once a book exists, and especially once it is employed in schoolrooms, people feel that the rules are not just descriptions of how people do talk, but prescriptions for how they should talk.

As we've seen, one reason the map is not the territory with language is because people feel compelled to play and experiment. When we encounter representations of systems involving people, we should keep in mind that while we may need rules for the sake of working together and understanding each other, we're always pushing up against and reshaping those rules. We find it boring to follow a rigid prescription.

For instance, imagine some of the documents you might receive upon starting a role at a new company. Process documents showing step by step how to do the main tasks you'll be expected to perform. But when the person you're replacing shows you how to do those same tasks, you notice they don't follow the listed steps at all. When you ask why, they explain that the process documents were written before they started actually carrying out those tasks, meaning they discovered more efficient ways afterward.

Why keep the process documents, then? Because for someone filling in or starting out, it might make sense to follow them. It's the most defensible option. Once you truly know the territory and won't change something without considering why it was there in the first place, you can play with the rules. Those documents might be useful as a description, but they're unlikely to remain a prescription for long.

The same is true for laws. Sometimes aspects of them are just descriptive of how things are at one point in time, but we end up having to keep following them to the letter because they haven't been updated. A law might have been written at a time when documents needed sending by letter, meaning certain delays for shipping. Now they can be sent by email. If the law hasn't been updated, those delay allowances turn from descriptions into prescriptions. Or a law might reflect what people were permitted to do at the time, but now we assume people should have the right to do that thing even if we have new evidence it's not the best idea. We are less likely to change laws if we persist in viewing them as prescriptive.

Conclusion

Descriptions of reality are practical for helping us navigate it, while also giving us room to change things. Prescriptions are helpful for giving us ways of understanding each other and providing enough structure for shared conventions, but they can also become outdated or end up limiting flexibility. When you encounter a representation of something, it's useful to consider which parts are descriptive and which parts are prescriptive. Remember that both prescriptions and descriptions can and should change over time.

149. Mental Models for Career Changes

Career changes are some of the biggest moves we will ever make, but they don't have to be daunting. Using mental models to make decisions we determine where we want to go and how to get there. The result is a change that aligns with the person we are, as well as the person we want to be.

We've all been there: you're at a job, and you know it's not for you anymore. You come in drained, you're not excited on a Monday morning, and you feel like you could be using your time so much better. It's not the people, and it's not the organization. It's the work. It's become boring, unfulfilling, or redundant, and you know you want to do something different. But what?

Just deciding to change careers doesn't get you very far because there are more areas to work in than you know about. A big change often involves some retraining. A career shift will impact your personal life. At the end of it all, you want to be happier but know there are no guarantees. How do you find a clear path forward?

No matter how ready you think you are to make a move, career changes are daunting. The stress of leaving what you're comfortable with to venture into foreign territory stops many people from taking the first step toward something new.

It doesn't have to be this way.

Using mental models can help you clarify the direction you want to go and plan for how to get there. They are tools that will give you more control over your career and more confidence in your decisions. When you do the work up front by examining your situation through the lens of a few mental models, you set yourself up for fewer regrets and more satisfaction down the road.

Get in touch with yourself

Before you can decide which change to make, you need to get in touch with yourself. No change will be the right one if it doesn't align with what you want to get out of life.

First, do you know where you want to go? Are you moving with direction or just moving?

As a mental model, velocity reminds us there is a difference between speed and direction. It's easy to move fast without getting anywhere. We can stay busy all day without achieving our goals. Without considering our velocity, we run a huge risk of getting sidetracked by things that make us move faster (more money, a title on a business card) without that movement actually leading us where we want to end up.

As the old saying goes, we want to run *to* something, not *from* something. When you start articulating your desired direction, you give yourself clear purpose in your career. It will be easier to play the long game because you know that everything you are doing is leading somewhere you want to be.

When it comes to changing careers, there are a lot of options. Using the mental model of velocity will help you focus on and identify the best opportunities.

Once you know where you want to end up, it's often useful to work backward to where you are now. This is known as inversion. Start at the end and carefully consider the events that get you there in reverse order.

For example, it could be something as simple as waking up happy and excited to work every day. What needs to be true in order for that to be a reality? Are you working from home, having a quiet cup of coffee as you prepare to do some creative work? Are you working on projects aligned with your values? Are you contributing to making the world a better place? Are you in an intense, collaborative team environment?

Doing an inversion exercise helps you identify the elements needed for you to achieve success. Once you identify your requirements, you can use that list to evaluate opportunities that come up.

Inversion will help you recognize critical factors, like finances or the support of your family, that will be necessary to get to where you want to go. If your dream direction requires you to learn a new skill or work at a junior level while you ramp up on the knowledge you'll need, you might need to live off some savings in the short term. Inversion, combined with velocity, will help you create the foundation you need now to take action when the right time comes.

Finally, the last step before you start evaluating the career environment is taking stock of the skills you already have. Why do you need to do this? So you know what you can repurpose. Here, you're using the concept of exaptation, which is part of the broader adaptation model in biology. Exaptation refers to traits that evolved for one purpose and then, through natural selection, were used for completely unrelated capabilities. For instance, feathers probably evolved for insulation. It was only much later that they turned out to be useful for flying.

History is littered with examples of technologies or tools invented for one purpose that later became the foundation for something completely different. Did you know that Play-Doh was originally created to clean coal soot off walls? And bubble wrap was originally envisioned as material for shower curtains.

Using this model is partly about getting out of the "functional fixedness" mindset. You want to look at your skills, talents, and knowledge and ask of each one: what else could this be used for?

Too often we fail to realize just how versatile the experience we've built up over the years is. We're great at using forks to eat, but they can also be used to brush hair, dig in a garden, and pin things to walls. Being great at presenting the monthly status update doesn't mean you're good at presenting monthly status updates. Rather, it means you can articulate yourself well, parse information for a diverse audience, and build networks to get the right information. Now, what else can those skills be used for?

Evaluate the environment

Looking at different careers, we're usually in a situation where the "map is not the territory." It's hard to know how great (or terrible) a job is until you actually do it. We often have two types of maps for the careers we wish we had: maps of the highlights, success stories, and opinions of people who love the work and maps based on how much we love the field or discipline ourselves.

The territory of the day-to-day work of these careers, however, is very different from what those two maps tell us.

In order to determine if a particular career will work for us, we need better maps. For example, the reality of being an actor isn't just the movies and programs you see them in. It's audition after audition, with more rejections than roles. It's intense competition and job insecurity. Being a research scientist at a university isn't just immersing yourself in a subject you love. It's grant applications and teaching and navigating the bureaucracy of academia.

In order to build a more comprehensive map of your dream job, do your research on as large a sample size as possible. Talk to people doing the job you want. Talk to people who work in the organization. Talk to the ones that enjoy it. Talk to the ones who quit. Try to get an accurate picture of what the day-to-day is like.

Very few jobs are one-dimensional. They involve things like administrative tasks, networking, project management, and accountability. How much of your day will be spent doing paperwork or updating your coworkers? How much of a connection do you need to maintain with people outside the organization? How many people will you be dependent on? What are they like? And who will you be working for?

It's not a good idea to become a writer just because you want to tell stories, open a restaurant just because you like to cook, or become a landscape designer just because

you enjoy being outside. Those motivations are good places to start—because it's equally terrible to become a lawyer just because your parents wanted you to. But you can't stop with what you like. There isn't a job in the world that's pleasurable and fulfilling 100% of the time.

You give yourself a much higher chance of being satisfied with your career change if you take the time to learn as much as you can about the territory beforehand.

Elements of planning

You know which direction you're heading in, and you've identified a great new career possibility. Now what?

Planning for change is a crucial component of switching careers. Two models, global and local maxima and activation energy, can help us identify what we need to plan.

Global and local maxima refers to the high values in a mathematical function. On a graph, it's a wavy curve with peaks and valleys. The highest peak in a section is a local maximum. The highest peak across the entire graph is the global maximum. Activation energy comes from chemistry, and is the amount of energy needed to see a reaction through to its conclusion.

One of the things global and local maxima teaches us is that sometimes you have to go down a hill in order to climb up a new one. To move from a local maximum to a higher peak you have to go through a local minimum, a valley. Too often we just want to go higher right away, or at the very least we want to make a lateral move. We perceive going down as taking a step backward.

A common problem is when we tie our self-worth to our salary and therefore reject any opportunities that won't pay us as much as we're currently making. The same goes for job titles; no one wants to be a junior anything in their mid-forties. But it's impossible to get to the next peak if we won't walk through the valley.

If you look at your career change through the lens of global and local maxima, you will see that steps down can also be steps forward.

Activation energy is another great model to use in the planning phase because it requires you to think about the real effort required for sustained change. You need to plan not just for making a change but also for seeing it through until the new thing has time to take hold. Do you have enough in the bank to support yourself if you need to retrain or take a pay cut? Do you have the emotional support to help you through the challenges of taking on a brand-new career?

Just like fires don't start with one match and a giant log, you have to plan for what you need between now and your desired result. What do you need to keep that reaction going so the flame from the match leads to the log catching fire? The same kind of thinking needs to inform your planning. After you've taken the first step, what will you need to keep you moving in the direction you want to go?

After you've done all the work

After getting in touch with yourself, doing all your research, identifying possible paths, and planning for what you need to do to walk them to the end, it can still be hard to make a decision. You've uncovered so many nuances and encountered so many ideas that you feel overwhelmed. The reality is, when it comes to career change, there often is no perfect decision. You likely have more than one option, and whatever you choose, there's going to be a lot of work involved.

One final model you can use is probabilistic thinking. In this particular situation, it can be helpful to use a Bayesian casino.

A Bayesian casino is a thought experiment where you imagine walking up to a casino game, like roulette, and quantifying how much you would bet on any particular outcome.

Let's say when investigating your career change, you've narrowed it down to two options. Which one would you bet on for being the better choice one year later? And how much would you part with? If you'd bet ten dollars on black, then you probably need to take a fresh look at the research you've done. Maybe go talk to more people, or broaden your thinking. If you're willing to put down thousands of dollars on red, that's very likely the right decision for you.

It's important in this thought experiment to fully imagine yourself making the bet. Imagine the money in your bank account. Imagine withdrawing it and physically putting it down on the table. How much you're willing to part with regarding a particular career choice says a lot about how good that choice is likely to be for you.

Probabilistic thinking isn't a predictor of the future. With any big career move, there are inevitably a lot of unknowns. There are no guarantees that any choice is going to be the right one. The Bayesian casino just helps you quantify your thinking based on the knowledge you have at this moment in time.

As new information comes in, return to the casino and see if your bets change.

Conclusion

Career changes are some of the biggest moves we will ever make, but they don't have to be daunting. Using mental models helps us find both the direction we want to go and a path we can take to get there. The result is a change that aligns with the person we are, as well as the person we want to be.

150. Thought Experiment: How Einstein Solved Difficult Problems

Thought experiments are a classic tool used by many great thinkers. They enable us to explore impossible situations and predict their implications and outcomes. Mastering thought experiments can help you confront difficult questions and anticipate (and prevent) problems.

The purpose of a thought experiment is to encourage speculation, logical thinking and to change paradigms. Thought experiments push us outside our comfort zone by forcing us to confront questions we cannot answer with ease. They demonstrate gaps in our knowledge and help us recognize the limits of what can be known.

"All truly wise thoughts have been thought already thousands of times; but to make them truly ours, we must think them over again honestly, until they take root in our personal experience."

Johann Wolfgang von Goethe

Famous thought experiments

Thought experiments have a rich and complex history, stretching back to the ancient Greeks and Romans.

An early example of a thought experiment is Zeno's narrative of Achilles and the tortoise, dating to around 430 BC. Zeno's thought experiments aimed to deduce first principles through the elimination of untrue concepts.

In one instance, the Greek philosopher used it to 'prove' motion is an illusion. Known as the dichotomy paradox, it involves Achilles racing a tortoise. Out of generosity, Achilles gives the tortoise a 100m head start. Once Achilles begins running, he soon catches up on the head start. However, by that point, the tortoise has moved another 10m. By the time he catches up again, the tortoise will have moved further. Zeno claimed Achilles could never win the race as the distance between the pair would constantly increase.

Descartes conducted a thought experiment, doubting the existence of everything he could until there was nothing left he could doubt. Descartes could doubt everything except for the fact that he could doubt. His process left us with the philosophical thought experiment of 'a brain in a vat'.

In the 17th century, Galileo used thought experiments to affirm his theories. One example is his thought experiment involving two balls (one heavy, one light) which are dropped from the Leaning Tower of Pisa. Prior philosophers had theorized the heavy ball would land first. Galileo claimed this was untrue, as mass does not influence acceleration.

According to Galileo's early biography (written in 1654), he dropped two objects from the Leaning Tower of Pisa to disprove the gravitational mass relation hypothesis. Both landed

at the same time, ushering in a new understanding of gravity. It is unknown if Galileo performed the experiment itself, so it is regarded as a thought experiment, not a physical one.

In 1814, Pierre Laplace explored determinism through 'Laplace's demon.' This is a theoretical 'demon' which has an acute awareness of the location and movement of every single particle in existence. Would Laplace's demon know the future? If the answer is yes, the universe must be linear and deterministic. If no, the universe is nonlinear and free will exists.

In 1897, the German term 'Gedankenexperiment' passed into English and a cohesive picture of how thought experiments are used worldwide began to form.

Albert Einstein used thought experiments for some of his most important discoveries. The most famous of his thought experiments was on a beam of light, which was made into a brilliant children's book. What would happen if you could catch up to a beam of light as it moved he asked himself? The answers led him down a different path toward time, which led to the special theory of relativity.

Natural tendencies

In On Thought Experiments, 19th-century Philosopher and physicist Ernst Mach writes that curiosity is an inherent human quality. Babies test the world around them and learn the principle of cause and effect. With time, our exploration of the world becomes more and more in depth. We reach a point where we can no longer experiment through our hands alone. At that point, we move into the realm of thought experiments.

Thought experiments are a structured manifestation of our natural curiosity about the world.

Mach writes:

Our own ideas are more easily and readily at our disposal than physical facts. We experiment with thought, so as to say, at little expense. It shouldn't surprise us that, oftentimes, the thought experiment precedes the physical experiment and prepares the way for it... A thought experiment is also a necessary precondition for a physical experiment. Every inventor and every experimenter must have in his mind the detailed order before he actualizes it.

Mach compares thought experiments to the plans and images we form in our minds before commencing an endeavor. We all do this — rehearsing a conversation before having it, planning a piece of work before starting it, figuring out every detail of a meal before cooking it. Mach views this as an integral part of our ability to engage in complex tasks and to innovate creatively.

According to Mach, the results of some thought experiments can be so certain that it is unnecessary to physically perform it. Regardless of the accuracy of the result, the desired purpose has been achieved.

"It can be seen that the basic method of the thought experiment is just like that of a physical experiment, namely, the method of variation. By varying the circumstances (continuously, if possible) the range of validity of an idea (expectation) related to these circumstances is increased."

Ernst Mach

Thought experiments in philosophy

Thought experiments have been an integral part of philosophy since ancient times. This is in part due to philosophical hypotheses often being subjective and impossible to prove through empirical evidence.

Philosophers use thought experiments to convey theories in an accessible manner. With the aim of illustrating a particular concept (such as free will or mortality), philosophers explore imagined scenarios. The goal is not to uncover a 'correct' answer, but to spark new ideas.

An early example of a philosophical thought experiment is Plato's Allegory of the Cave, which centers around a dialogue between Socrates and Glaucon (Plato's brother.) A group of people are born and live within a dark cave. Having spent their entire lives seeing nothing but shadows on the wall, they lack a conception of the world outside. Knowing nothing different, they do not even wish to leave the cave. At some point, they are led outside and see a world consisting of much more than shadows.

Plato used this thought experiment to illustrate the incomplete view of reality most of us have. Only by learning philosophy, Plato claimed, can we see more than shadows.

Upon leaving the cave, the people realize the outside world is far more interesting and fulfilling. If a solitary person left, they would want others to do the same. However, if they return to the cave, their old life will seem unsatisfactory. This discomfort would become misplaced, leading them to resent the outside world. Plato used this to convey his (almost compulsively) deep appreciation for the power of educating ourselves. To take up the mantle of your own education and begin seeking to understand the world is the first step on the way out of the cave.

Moving from caves to insects, here's a thought experiment from 20th-century philosopher Ludwig Wittgenstein.

Imagine a world where each person has a beetle in a box. In this world, the only time anyone can see a beetle is when they look in their own box. As a consequence, the conception of a beetle each individual has is based on their own. It could be that everyone has something different, or that the boxes are empty, or even that the contents are amorphous.

Wittgenstein uses the 'Beetle in a Box' thought experiment to convey his work on the subjective nature of pain. We can each only know what pain is to us, and we cannot feel another person's agony. If people in the hypothetical world were to have a discussion on the topic of beetles, each would only be able to share their individual perspective. The conversation would have little purpose because each person can only convey what they see as a beetle. In the same way, it is useless for us to describe our pain using analogies ('it feels like a red hot poker is stabbing me in the back') or scales ('the pain is 7/10.')

Thought experiments in science

Although empirical evidence is usually necessary for science, thought experiments may be used to develop a hypothesis or to prepare for experimentation. Some hypotheses cannot be tested (e.g, string theory) – at least, not given our current capabilities. Theoretical scientists may turn to thought experiments to develop a provisional answer, often informed by Occam's razor.

In a paper entitled Thought Experimentation of Presocratic Philosophy, Nicholas Rescher writes:

In natural science, thought experiments are common. Think, for example, of Einstein's pondering the question of what the world would look like if one were to travel along a ray of light. Think too of physicists' assumption of a frictionlessly rolling body or the economists' assumption of a perfectly efficient market in the interests of establishing the laws of descent or the principles of exchange, respectively.

In a paper entitled Thought Experiments in Scientific Reasoning, Andrew D. Irvine explains that thought experiments are a key part of science. They are in the same realm as physical experiments. Thought experiments require all assumptions to be supported by empirical evidence. The context must be believable, and it must provide useful answers to complex questions. A thought experiment must have the potential to be falsified.

Irvine writes:

Just as a physical experiment often has repercussions for its background theory in terms of confirmation, falsification or the like, so too will a thought experiment. Of course, the parallel is not exact; thought experiments...no do not include actual interventions within the physical environment.

In Do All Rational Folks Think As We Do? Barbara D. Massey writes:

Often critique of thought experiments demands the fleshing out or concretizing of descriptions so that what would happen in a given situation becomes less a matter of guesswork or pontification. In thought experiments we tend to elaborate descriptions with the latest scientific models in mind...The thought experiment seems to be a close relative of the scientist's laboratory experiment with the vital difference that observations may be made from perspectives which are in reality impossible, for example, from the perspective of moving at the speed of light...The thought experiment seems to discover facts about how things work within the laboratory of the mind.

"We live not only in a world of thoughts, but also in a world of things. Words without experience are meaningless."

Vladimir Nabokov

Biologists use thought experiments, often of the counterfactual variety. In particular, evolutionary biologists question why organisms exist as they do today. For example, why are sheep not green? As surreal as the question is, it is a valid one. A green sheep would be better camouflaged from predators. Another thought experiment involves asking: why don't organisms (aside from certain bacteria) have wheels? Again, the question is surreal but is still a serious one. We know from our vehicles that wheels are more efficient for moving at speed than legs, so why do they not naturally exist beyond the microscopic level?

Psychology and Ethics — The Trolley Problem

Picture the scene. You are a lone passerby in a street where a tram is running along a track. The driver has lost control of it. If the tram continues along its current path, the five passengers will die in the ensuing crash. You notice a switch which would allow the tram to move to a different track, where a man is standing. The collision would kill him but would save the five passengers. Do you press the switch?

The Trolley Problem was first suggested by philosopher Phillipa Foot, and further considered extensively by philosopher Judith Jarvis Thompson. Psychologists and ethicists have also discussed the trolley problem at length, often using it in research. It raises many questions, such as:

- Is a casual observer required to intervene?
- Is there a measurable value to human life? I.e. is one life less valuable than five?
- How would the situation differ if the observer were required to actively push a man onto the tracks rather than pressing the switch?

- What if the man being pushed were a 'villain'? Or a loved one of the observer? How would this change the ethical implications?
- Can an observer make this choice without the consent of the people involved?

Research has shown most people are far more willing to press a switch than to push someone onto the tracks. This changes if the man is a 'villain' - people are then far more willing to push him. Likewise, they are reluctant if the person being pushed is a loved one. The trolley problem is theoretical, but it does have real world implications. As we move towards autonomous vehicles, there may be real life instances of similar situations. Vehicles may be required to make utilitarian choices – such as swerving into a ditch and killing the driver to avoid a group of children.

The Infinite Monkey Theorem and Mathematics

"Ford!" he said, "there's an infinite number of monkeys outside who want to talk to us about this script for Hamlet they've worked out."

Douglas Adams, *The Hitchhiker's Guide to the Galaxy*

In Fooled By Randomness, Nassim Taleb writes:

If one puts an infinite number of monkeys in front of (strongly built) typewriters, and lets them clap away, there is a certainty that one of them will come out with an exact version of the 'Iliad.' Upon examination, this may be less interesting a concept than it appears at first: Such probability is ridiculously low. But let us carry the reasoning one step beyond. Now that we have found that hero among monkeys, would any reader invest his life's savings on a bet that the monkey would write the 'Odyssey' next?

The infinite monkey theorem is intended to illustrate the idea that any issue can be solved through enough random input, in the manner a drunk person arriving home will eventually manage to fit their key in the lock even if they do it without much finesse. It also represents the nature of probability and the idea that any scenario is workable, given enough time and resources.

151. 5 Mental Models to Remove (Some of) the Confusion from Parenting

We often talk about mental models in the context of business, investing, and careers. But mental models can also help with other areas, like parenting. Here are 5 principle-based models you can apply to any family, any situation, and any child.

Just a few days ago, I saw a three-year-old wandering around at 10:30 at night and wondered if he was lost or jet-lagged. The parent came over and explained that they believed in children setting their own sleep schedule.

Interesting.

The problem with this approach is that it may work, or it may not. It may work for your oldest, but not your youngest. And therein lies the problem with the majority of the parenting advice available. It's all tactics, no principles.

Few topics provoke more unsolicited advice than parenting. The problem is, no matter how good the advice, it might not work for your child. Parenting is the ultimate "the map is not the territory" situation. There are so many maps out there, and often when we try to use them to navigate the territory that is each individual child, we end up lost and confused. As in other situations, when the map doesn't match the territory, better to get rid of the map and pay attention to what you are experiencing on the ground. The territory is the reality. We've all dealt with the seemingly illogical behavior of children. Take trying to get your child to sleep through the night—often the first, and most important, challenge. Do you sleep beside them and slowly work your way out of the room? Do you let them "cry it out?" Do you put them in your bed? Do you feed them on demand, or not until morning? Soft music or no music? The options are endless, and each of them has a decently researched book to back it up.

When any subsequent children come along, the problem is often exacerbated. You stick to what worked the first time, because it worked, but this little one is different. Now you're in a battle of wills, and it's hard to change your tactics at 3:00 a.m. Parenting is often a rinse and repeat of this scenario: ideas you have about how it should be, combined with what experience is telling you that it is, overlaid with too many options and chronic exhaustion. This is where mental models can help. As in any other area of your life, developing some principles or models that help you see how the world works will give you options for relevant and useful solutions. Mental models are amazing tools that can be applied across our lives. Here are five principle-based models you can apply to almost any family, situation, or child. These are ones I use often, but don't let this limit you—so many more apply!

1. Adaptation

Adaptation is a concept from evolutionary biology. It describes the development of genetic traits that are successful relative to their performance in a specific environment—that is, relative to organisms' survival in the face of competitive pressures. As Geerat Vermeij explains in Nature: An Economic History, "Adaptation is as good as it has to be; it need not be the best that could be designed. Adaptation depends on context."

In terms of parenting, this is a big one: the model we can use to stop criticizing ourselves for our inevitable parenting mistakes, to get out of the no-point comparisons with our peers, and to give us the freedom to make changes depending on the situation we find ourselves in.

Species adapt. It is a central feature of the theory of evolution—the ability of a species to survive and thrive in the face of changing environmental conditions. So why not apply this basic biological idea to parenting? Too often we see changing as a weakness. We're certain that if we aren't absolutely consistent with our children, they will grow up to be entitled underachievers or something. Or we put pressure on ourselves to be perfect, and

strive for an ideal that requires an insane amount of work and sacrifice that may actually be detrimental to our overall success.

We can get out of this type of thinking if we reframe 'changing' as 'adapting'. It's okay to have different rules in the home versus a public space. I am always super grateful when a parent pacifies a screaming child with a cookie, especially on an airplane or in a restaurant. They probably don't use the same strategy at home, but they adapt to the different environment. It's also okay to have two children in soccer, and the third in music. Adapting to their interests will offer a much better return of investment on all those lessons. No doubt your underlying goals for your children are consistent, like the desire of an individual to survive. How you meet those goals is where the adaptability comes in. Give yourself the freedom to respond to the individual characteristics of your children—and the specific needs of the moment—by trying different behaviors to see what works. And, just as with adaptation in the biological sense, you only need to be as good as you have to be to get the outcomes that are important to you, not be the best parent that ever was.

2. Velocity

There is a difference between speed and velocity. With speed you move, but with velocity you move somewhere. You have direction.

As many have said of parenting, the days are long but the years are short. It's hard to be focusing on your direction when homework needs to be done and dinner needs to get made before one child goes off in the carpool to soccer while you rush the other one to art class. Every day begins at a dead run and ends with you collapsing into bed only to go through it all again tomorrow. Between their activities and social lives, and your need to work and have time for yourself, there is no doubt that you move with considerable speed throughout your day.

But it's useful to sometimes ask, 'Where am I going?' Take a moment to make sure it's not all speed and no direction.

When it comes to time with your kids, what does the goal state look like? How do you move in that direction? If you are just speeding without moving then you have no frame of reference for your choices. You might ask, did I spend enough time with them today? But ten minutes or two hours isn't going to impact your velocity if you don't know where you are headed.

When you factor in a goal of movement, it helps you decide what to do when you have time with them. What is it you want out of it? What kind of memories do you want them to have? What kind of parent do you want to be and what kind of children do you want to raise? The answers are different for everyone, but knowing the direction you wish to go helps you evaluate the decisions you make. And it might have the added benefit of cutting out some unnecessary activity and slowing you down.

3. Algebraic Equivalence

"He got more pancakes than I did!" Complaints about fairness are common among siblings. They watch each other like hawks, counting everything from presents to hugs to make sure everyone gets the same. What can you do? You can drive yourself mad running out to buy an extra whatever, or you can teach your children the difference between 'same' and 'equal'.

If you haven't solved for x in a while, it doesn't really matter. In algebra, symbols are used to represent unknown numbers that can be solved for given other relevant information. The general point about algebraic equivalence is that it teaches us that two things need not be the same in order to be equal.

For example, $x + y = 5$. Here are some of the options for the values of x and y :

$$3 + 2$$

$$4 + 1$$

$$2.5 + 2.5$$

$$1.8 + 3.2$$

And those are just the simple ones. What is useful is this idea of abstracting to see what the full scope of possibilities are. Then you can demonstrate that what is on each side of those little parallel lines doesn't have to look the same to have equal value. When it comes to the pancakes, it's better to focus on an equal feeling of fullness than the number of pancakes on the plate.

In a deeper way, algebraic equivalence helps us deal with one accusation that all parents get at one time or another: "You love my sibling more than me." It's not true, but our default usually is to say, "No, I love you both the same." This can be confusing for children, because, after all, they are not the same as their sibling, and you likely interact with them differently, so how can the love be the same?

Using algebraic equivalence as a model shifts it. You can respond instead that you love them both equally. Even though what's on either side of the equation is different, it is equal. Swinging the younger child up in the air is equivalent to asking the older one about her school project. Appreciating one's sense of humor is equivalent to respecting the other's organizational abilities. They may be different, but the love is equal.

4. Seizing the Middle

In chess, the middle is the key territory to hold. As explained on [Wikipedia](#): "The center is the most important part of the chessboard, as pieces from the center can easily move to either flank with great speed. However, amateurs often prefer to concentrate on the king's side of the board. This is an incorrect mindset."

In parenting, seizing the middle means you must forget trying to control every single move. It's impossible anyway. Instead, focus on trying to control what I think of as the middle territory. I don't mind losing a few battles on the fringes, if I'm holding my ground in the area that will allow me to respond quickly to problems.

The other night my son and I got into perhaps our eighth fight of the week on the state of his room. The continual explosion makes it hard to walk in there, plus he loses things all the time, which is an endless source of frustration to both of us. I've explained that I hate buying replacements only to have them turn up in the morass months later.

So I got cranky and got on his case again, and he felt bad and cried again. When I went to the kitchen to find some calm, I realized that my strategy was all wrong. I was focused on the pawn in the far column of the chess board instead of what the pieces were doing right in front of me.

My thinking then went like this: what is the territory I want to be present in? Continuing the way I was would lead to a clean room, maybe. But by focusing on this flank I was sacrificing control of the middle. Eventually he was going to tune me out because no one wants to feel bad about their shortcomings every day. Is it worth saving a pawn if it leaves your queen vulnerable?

The middle territory with our kids is mutual respect and trust. If I want my son to come to me for help when life gets really complicated, which I do, then I need to focus on behaviors that will allow me to have that strategic influence throughout my relationship with him.

Making him feel like crap every day, because his shirts are mixed in with his pants or because of all the Pokemon cards are on the floor, isn't going to cut it. Make no mistake, seizing the middle is not about throwing out all the rules. This is about knowing which battles to fight, so you can keep the middle territory of the trust and respect of your child.

5. Inversion

Sometimes it's not about providing solutions, but removing obstacles. Sociologist Kurt Lewin observes in his work on force field analysis^[1] that reaching any goal has two components: augmenting the forces for, and removing the forces against. When it comes to parenting, we need to ask ourselves not only what we could be doing more of, but also what we could be doing less of.

When my friend was going on month number nine of her baby waking up four times a night, she felt at her wits' end. Out of desperation, she decided to invert the problem. She

had been trying different techniques and strategies, thinking that there was something she wasn't doing right. When nothing seemed to be working, she stopped trying to add elements like new tactics, and changed her strategy. She looked instead for obstacles to remove. Was there anything preventing the baby from sleeping through the night? The first night she made it darker. No effect. The second night she made it warmer. Her son has slept through the night ever since. It wasn't her parenting skills or the adherence to a particular sleep philosophy that was causing him to wake up so often. Her baby was cold. Once she removed that obstacle with a space heater the problem was resolved. We do this all the time, trying to fix problem by throwing new parenting philosophies at the situation. What can I do better? More time, more money, more lessons, more stuff. But it can be equally valuable to look for what you could be doing less of. In so doing, you may enrich your relationships with your children immeasurably. Parenting is inherently complex: the territory changes almost overnight. Different environments, different children—figuring out how to raise your kids plays out against a backdrop of some fast-paced evolution. Some tactics are great, and once in a while a technique fits the situation perfectly. But when your tactics fail, or your experience seems to provide no obvious direction, a principle-based mental models approach to parenting can give you the insight to find solutions as you go.

152. Predicting the Future with Bayes' Theorem

In episode #37 of The Knowledge Project, we talked with professional poker player Annie Duke about thinking in probabilities, something good poker players do all the time. At the poker table or in life, it's useful to think in probabilities versus absolutes based on all the information you have available to you.

Probabilistic thinking leads you to ask yourself, how confident am I in this prediction? What information would impact this confidence?

Bayes' Theorem

Bayes' theorem is an accessible way of integrating probability thinking into our lives.

Thomas Bayes was an English minister in the 18th century, whose most famous work, "*An Essay toward Solving a Problem in the Doctrine of Chances*," was brought to the attention of the Royal Society in 1763—two years after his death—by his friend Richard Price. The essay did not contain the theorem as we now know it but had the seeds of the idea. It looked at how to adjust our estimates of probabilities when encountering new data that influence a situation. Later development by French scholar Pierre-Simon Laplace and others helped codify the theorem and develop it into a useful tool for thinking.

Knowing the exact math of probability calculations is not the key to understanding Bayesian thinking. More critical is your ability and desire to assign probabilities of truth and accuracy to anything you think you know, and then being willing to update those probabilities when new information comes in.

Here is a short example, found in Investing: The Last Liberal Art, of how it works:

Let's imagine that you and a friend have spent the afternoon playing your favorite board game, and now, at the end of the game, you are chatting about this and that. Something your friend says leads you to make a friendly wager: that with one roll of the die from the game, you will get a 6. Straight odds are one in six, a 16 percent probability. But then suppose your friend rolls the die, quickly covers it with her hand, and takes a peek. "I can tell you this much," she says; "it's an even number." Now you have new information and your odds change dramatically to one in three, a 33 percent probability. While you are considering whether to change your bet, your friend teasingly adds: "And it's not a 4." With this additional bit of information, your odds have changed again, to one in two, a 50 percent probability. With this very simple example, you have performed a Bayesian analysis. Each new piece of information affected the original probability, and that is Bayesian [updating].

Both Nate Silver and Eliezer Yudkowsky have written about Bayes' theorem in the context of medical testing, specifically mammograms. Imagine you live in a country with 100 million women under 40. Past trends have revealed that there is a 1.4% chance of a woman under 40 in this country getting breast cancer—so roughly 1.4 million women. Mammograms will detect breast cancer 75% of the time. They will give out false positives—say a woman has breast cancer when she actually doesn't—about 10% of the time. At first, you might focus just on the mammogram numbers and think that a 75% success rate means that a positive is bad news. Let's do the math.

If all the women under 40 get mammograms, then the false positive rate will give 10 million women under 40 the news that they have breast cancer. But because you know the first statistic, that only 1.4 million women under 40 actually get breast cancer, you know that 8.6 million of the women who tested positive are not actually going to have breast cancer!

That's a lot of needless worrying, which leads to a lot of needless medical care. To remedy this poor understanding and make better decisions about using mammograms, we absolutely must consider prior knowledge when we look at the results, and try to update our beliefs with that knowledge in mind.

Weigh the Evidence

Often we ignore prior information, simply called “priors” in Bayesian-speak. We can blame this habit in part on the availability heuristic—we focus on what’s readily available. In this case, we focus on the newest information, and the bigger picture gets lost. We fail to adjust the probability of old information to reflect what we have learned.

The big idea behind Bayes’ theorem is that we must continuously update our probability estimates on an as-needed basis.

In their book The Signal and the Noise, Nate Silver and Allen Lane give a contemporary example, reminding us that new information is often most useful when we put it in the larger context of what we already know:

Bayes’ theorem is an important reality check on our efforts to forecast the future. How, for instance, should we reconcile a large body of theory and evidence predicting global warming with the fact that there has been no warming trend over the last decade or so? Skeptics react with glee, while true believers dismiss the new information.

A better response is to use Bayes’ theorem: the lack of recent warming is evidence against recent global warming predictions, but it is weak evidence. This is because there is enough variability in global temperatures to make such an outcome unsurprising. The new information should reduce our confidence in our models of global warming—but only a little.

The same approach can be used in anything from an economic forecast to a hand of poker, and while Bayes’ theorem can be a formal affair, Bayesian reasoning also works as a rule of thumb. We tend to either dismiss new evidence, or embrace it as though nothing else matters. Bayesians try to weigh both the old hypothesis and the new evidence in a sensible way.

Limitations of the Bayesian

Don’t walk away thinking the Bayesian approach will enable you to predict everything! In addition to seeing the world as an ever-shifting array of probabilities, we must also remember the limitations of inductive reasoning.

A high probability of something being true is not the same as saying it is true. Consider this example from Bertrand Russell’s The Problems of Philosophy:

A horse which has been often driven along a certain road resists the attempt to drive him in a different direction. Domestic animals expect food when they see the person who usually feeds them. We know that all these rather crude expectations of uniformity are liable to be misleading. The man who has fed the chicken every day throughout its life at last wrings its neck instead, showing that more refined views as to the uniformity of nature would have been useful to the chicken.

In the final analysis, though, picking up Bayesian reasoning can change your life, as observed in this Big Think video by Julia Galef of the Center for Applied Rationality:

After you’ve been steeped in Bayes’ rule for a little while, it starts to produce some fundamental changes to your thinking. For example, you become much more aware that your beliefs are grayscale. They’re not black and white and that you have levels of confidence in your beliefs about how the world works that are less than 100 percent but greater than zero percent and even more importantly as you go through the world and encounter new ideas and new evidence, that level of confidence fluctuates, as you encounter evidence for and against your beliefs.

So much of making better decisions hinges on dealing with uncertainty. The most common thing holding people back from the right answer is holding on to previous beliefs. Instead of instinctively rejecting new information, take in what comes your way through a system of evaluating probabilities.

153. Reciprocity: Getting What You Give

This article is an excerpt from the bestselling book The Great Mental Models Volume 2: Physics, Chemistry and Biology

Reciprocity teaches us why win-win relationships are the way to go, why waiters leave candies with the bill, why it's a good idea to use the least force possible to secure an outcome, and why a lot of companies don't permit their employees to accept gifts.

This model demonstrates why we should view giving as being as valuable as having. It prompts us rewrite the Golden Rule to say, "Do unto others knowing that something will be done unto you." So what exactly is reciprocity?

In physics, reciprocity is Newton's third law, which states that for every force exerted by object A on object B, there is an equal but opposite force exerted by object B on object A. Every force involves the interaction of two objects where the force asserted by one is reciprocated with an equally powerful and directionally opposite force by the other object. Forces always occur in pairs of the same type of force, and it is not possible for one object to exert a force without experiencing a reciprocal force.

For every action, there is an equal and opposite reaction.

Newton's third law

When I land on the ground after jumping, I am exerting a force on the ground. At the moment of landing, the ground is also applying a force that is equal but opposite in direction on me. The earth applies a force on me even when I am just standing. This force is gravity. But the gravitational force exerted on me by Earth is reciprocated by me through the force I am exerting on the earth.

In the natural world, this third law of Newton's explains jet propulsion. The word propulsion comes from two Latin terms meaning "forward" and "drive"—propulsion is a force that drives an object forward.¹ Jet propulsion works by forcing matter, such as gas produced by burning fuel, in one direction, leading to a corresponding movement of the vehicle in the opposite direction. This holds true for everything from fireworks and guns to huge spacecraft.

Jet propulsion only works if the forward push is stronger than the forces acting on the object, like air friction and its own weight. The greater the force in comparison to drag (the amount of force opposing the motion), the faster the object can move. Octopi and squid force water through their mantle and out through a siphon at a high speed that compensates for their weight and the viscosity of the water. As the animal asserts a force on the water, the water exerts a force on the animal, and this makes the octopus or squid move.

Consider the tackle in American football. The force that the defender puts on the receiver's body in order to bring him to the ground is equivalent to the force felt by the defenseman's body during the tackle. You can't initiate force without having a force put on you. For the tackle, this is very important. If the defenseman felt nothing there would be no incentive for him to be strategic in the application of his force on the receiver. And who would actually want to be a receiver if this were the case? If the guy who initiates the force feels nothing—much better to be him.

Since this is not the case, the tackle is more about using the least amount of force required to bring the receiver to the ground. It's better for the receiver, and it's also better for the guy doing the tackling, because the more force you apply to others, the more damage you do to yourself. Reciprocity can be summed up like this: when you act on things, they act on you.

What we give

It would be amazing if every time you did something good for the world, you received a corresponding amount of positive effect in your life. We all know that unfortunately this is not true. Sometimes positive intentions produce negative results, or bad things happen to people who do good things for others. Although the connection between good deeds and a good life isn't perfect, there is a documented relationship between the two. Using the model of reciprocity can help us understand why people benefit themselves when they work for what they believe is good. The life of Norman Bethune,* a Canadian surgeon, is one that can teach us a lot about the nuances of reciprocity.

Bethune was not a volunteer in the sense we often use the term now to describe activities that are an adjunct to daily life. His efforts to help others were completely integrated into his work and life. What made him a volunteer is that he did it of his own volition, at no obvious personal benefit. Therefore, his story provides an interesting example to really explore reciprocity. What do you get when you give? What kind of tensions are created when the two forces interact?

Norman Bethune grew up wanting to be a surgeon, inspired by his doctor grandfather. He completed his studies during the First World War, during which he also volunteered providing medical support on the battlefield. During the 1920s he practiced medicine in the United States and Canada, eventually settling in Montreal. He initially specialized in thoracic surgery and developed a solid reputation as a surgeon. However, he had an ongoing commitment to help people beyond what he did in his practice. This goal he pursued in a variety of ways.

During the early 1930s, while in Montreal, Bethune provided medical services free to the poor and established a free-of-charge clinic he ran once per week. He vocally advocated for universal health protection, explaining that many medical issues were created by poverty and negligent employers. In addition, and unique for the time, he used radio broadcasts to educate the public on tuberculosis. Bethune volunteered his time, energy, and intelligence to try to bring about meaningful improvements in the lives of the most impoverished.

During the 1930s he became a supporter of communism and joined the Communist Party, mostly on account of what he saw of the benefits of the Soviet socialized health care system. These political beliefs took him further afield in his efforts to improve access to and outcomes in healthcare.

In 1936 in Spain during the Spanish Civil War, Bethune designed and developed the first ever mobile blood transfusion unit. This vehicle could draw and store blood, was used to give transfusions, and most importantly, could be used on the front lines of the battlefield. It was a remarkable innovation that saved countless lives and inspired the medical approach used in World War II.

All of the work that Bethune did in Spain, and later China, was not for profit. The mobile blood unit and all his other surgical innovations and inventions did not make Bethune any money.

In 1938 Bethune went to China, desiring again to help people. China was fighting a war with the Japanese, the Sino-Japanese War, and Bethune's belief in communism led him to deploy his efforts in support of Mao and the Communist Party of China. He was made commander of all Chinese medical forces and immediately set about modernizing the existing primitive health care in China.

Helping the Chinese in their fight, he again deployed his practice of bringing the surgeon to the battlefield, designing mobile operating equipment and improving the survival rate of the injured. He also extensively trained doctors and nurses and established hospitals in areas that had neither. In their article, "The Medical Life of Norman Bethune," Deslauriers and Goulet write, "His courage, determination and will to fully employ his talents of ingenuity, aggressiveness and selfless response to social concerns when the time came is truly remarkable." He accomplished so much in his 18 months in China that when he died of septicemia after operating on a soldier, Mao delivered his eulogy, describing him as "a man who is of value to the people."

Bethune's achievements continue to be regarded as heroic by the Chinese. The first hospital he founded still exists, and his story is mandatory learning for primary school students in China.

Bethune's story, however, is not solely one of accolades and recognition, heaps of positive effects achieved as a result of a life spent trying to bring about good. He died at age 49 as a direct result of his efforts to improve health outcomes on the battlefield. The fact that he was a communist led him to be written out of Canadian history during the Cold War years, when communism was seen as a direct threat to Western democracy. His personal life wasn't great, and his aggressive personality earned him enmity from many colleagues. Many, many men have been just as troubled morally and spiritually as you are right now. Happily, some of them kept records of their troubles. You'll learn from them—if you want to. Just as someday, if you have something to offer, someone will learn something from you. It's a beautiful reciprocal arrangement.

j.d. salinger

Normally one would talk about a life like Norman Bethune's in terms of sacrifice. He sacrificed personal relationships, social acceptance, and ultimately his life in order to take actions in accord with his beliefs and values. But using the lens of reciprocity suggests there is another way to interpret the story.

In a paper on the health benefits of volunteering in adults, the authors explain, "The beneficial effects of volunteering on health outcomes have been well documented. Research has found that participation in voluntary services is significantly predictive of better mental and physical health, life satisfaction, self-esteem, happiness, lower depressive symptoms, psychological distress, and mortality and functional inability."⁶ Multiple studies have demonstrated the positive consequences of volunteering that are conferred on the volunteer. We may volunteer for a variety of reasons, based on our interests, goals or values, but regardless, we reap health benefits when we do so. The studies on the positive aspects of volunteering for the volunteer bring to mind the concepts we outlined above in the science of reciprocity, like how forces always occur in

pairs. Although volunteering is not governed by the laws of physics, using reciprocity as a metaphor can help us understand why volunteering appeals to so many people. And consequently, why some people make the choice to help others at seemingly great cost to themselves.

The research on volunteering makes it clear that when we give, we get. We improve our physical health; we feel better about ourselves and our place in the world. We evaluate our lives as having more meaning. One way of understanding people who take the kinds of actions that Bethune did, which on their face seem to risk so much, is that they receive a benefit from the world proportional to what they put out there. It's not a benefit that can always be measured in legacy or reward. Sometimes those things come; for Bethune, although North America struggled for decades to appreciate him as the dedicated medical innovator he was on account of his political views, China continues to go all out in its appreciation of his contributions to their country.

However, perhaps the benefit is better conceptualized as the reciprocity received by the individual in terms of the satisfaction they have regarding the choices they've made. The act of doing good causes an equal reaction in terms of feeling good. In reading Bethune's story it is clear that he was not motivated by recognition, but rather a genuine desire to help people that gave him an exceptional amount of energy and drive. It is highly possible that he didn't evaluate his life as one of sacrifice, but instead derived satisfaction from his efforts. (See tit-for-tat.)

The rise of the "win-win"

In the physical world, the law of reciprocity works 100% of the time. The harder you punch a wall, the more force pushes against your fist, the more damage is caused to both you and the wall. In the biological world, reciprocity doesn't have the same perfect record. However, it has been discovered to work much more often than not, and thus harnessing it has significant long-term benefits.

Evolutionary biologists argue that our tendency to engage in reciprocal behavior is a natural product of evolution. You are more likely to survive if you receive help from others. And you are more likely to receive that help if you have offered assistance in the past. So the genes that encode the reciprocal instinct were more likely to be passed on. And thus the fact that the human species has made it to now is directly dependent on our building social interactions that are reliable, useful, and trustworthy.

Humans engage in two types of reciprocity with each other: direct, which is "I help you and you help me;" and indirect, which is either a pay-it-forward concept, "I help you and then you help someone else," or more about reputation building—"I help you, building a reputation as one who helps, so that someone else helps me in the future." Both kinds work.

While reciprocity isn't as reliable when it comes to humans as it is with physics, the concept can help you achieve better outcomes. Sometimes we go first and go positive and get nothing back, as is the case if we smile at a stranger walking on the street. Most times they'll smile back at you, but every once in a while, you're met with a scowl. We tend to forget the times our smile elicited a smile in response and remember the times when we received nothing in return, and so we stop smiling. However, the small loss we occasionally experience as a result of putting ourselves out there and not having it reciprocated is more than compensated for by the gains the rest of the time. If you want to get an idea of the true value of engaging in positive reciprocal behavior, just make a list of your outcomes in any given week. Life is easier and more enjoyable when we act on starting and maintaining win-win relationships with everyone. And as we explained, reciprocity has been part of our biological makeup for a very long time.

Tsze-Kung asked, "Is there one word with which to act in accordance throughout a lifetime?" The Master said, "Is not reciprocity such a word? What you do not want done to yourself, do not do to others."

confucius

Let's go back to the eastern Mediterranean around 1250 BCE. The bulk of the power in the region was held by the four kings of Egypt, Hatti (a region in present day Turkey), Assyria and Babylon. They didn't like each other much—in fact, “they deeply distrusted each other and frequently squabbled.” Demonstrating military prowess was often a way that a king achieved legitimacy in the eyes of his subjects, and there were constant conflicts, from skirmishes to full-on battles between these four areas. Fighting was the norm.

Then, one day, as Trevor Bryce chronicles in his article on “The Eternal Treaty”, 15 years after a “great military showdown” between the Egyptians and the Hittites, an interesting thing happened. The two kings decided to enter into the world's first known peace treaty. The treaty was not about peace in the global sense, stemming from a desire to have a world without war. It was about peace in the immediate sense; two parties trying to establish a mutually beneficial relationship. The treaty, known as the Eternal Treaty, was the laying out of a directly reciprocal relationship between two civilizations.

Egypt was led by Ramesses, whose primary goal was to build “monumental construction projects, and to build his kingdom's wealth through trade and the exploitation of its mineral-rich regions.”¹⁰ He had other security issues, most notably the Libyans to the west. So his interest in the treaty was to give himself some space to accomplish the legacy that mattered to him. The reality is, if you're fighting with everyone all of the time you have to spread your resources along many fronts and you likely don't have time to do anything else. One less border to defend was an opportunity to put his efforts elsewhere.

The Hittites had a similar problem, in a growing military threat from the Assyrians. In addition, their ruler Hattusili had usurped the throne from his nephew and was badly in need of some external power to legitimize his rule. Ramesses commanded great respect in the region, and his acknowledgment of Hattusili's leadership would go a long way to maintaining stability. In pursuing the treaty with Egypt, “his hope was that Ramesses' endorsement of his own position, and by implication that of his lineal descendants, would provide some security against future challenges.”

The treaty contained provisions for future military support, the kind of alliance in which an attack on one is an attack on the other. Assyria, despite having both interest and a good position did not, in fact, invade Hatti during Hattusili's reign, so “quite possibly, the Egyptian-Hittite alliance did prove an effective deterrent against such an enterprise.”

Reciprocity based on self-interest is still reciprocity. Engaging in positive behavior to then be a receiver of positive behavior is about the long game. For both Ramesses and Hattusili, the benefits of trying to develop an alliance were clear. It gave them both an opportunity to exit fighting that consumed resources and allowed them to focus those resources on long-term stability and their legacies. Over time, the likelihood of reciprocal interactions increases, and thus it's a much better strategy to try to make them positive. The more people you help, the more people you will have willing to help you.

154. Tit For Tat

Tit for tat is a strategy which, according to game theory, is the most effective choice for iterated games based on mutual cooperation or defection. Both players benefit if they cooperate, but one benefits and the other loses out if only they defect, and both lose out to a lesser extent if they simultaneously defect. As abstract as such games sound, they have important implications for understanding everything from group selection in biology to cooperation in economics.

Under tit for tat, a player will begin by cooperating, then in subsequent iterations will replicate whatever their opponent did last time. So if their initial cooperation is punished with defection, they will then reciprocate in kind. In games that are not iterated and only consist of a single round, defection is thought to be the best strategy.

Tit for tat was codified as a game theory strategy by mathematical psychologist Anatol Rapoport, but it builds upon our instinctual notions of reciprocity. It teaches us that our best option when dealing with other people we cannot trust entirely is to reciprocate their choices. Seeing as we can rarely place full trust in anyone, especially if they stand to gain by screwing us over, we lean toward tit for tat. In general, we view this as fair and just. If someone helps us, we're quite happy to assist them the next time they need help. But if they ignore our plight when we need help, we're highly unlikely to care in the inverse situation. For this reason, evolution tends to select for cooperative behavior in groups—it benefits everyone in the long run.

However, straightforward tit for tat is not as effective as the strategy known as tit for tat with forgiveness. This strategy involves occasionally cooperating in the face of defection. It is easy for two opponents to get stuck in a cycle of mutual defection from which they cannot escape unless and until one decides to cooperate. If both are using tit for tat, a cycle of mutual cooperation will then commence.

Life is an iterative and compounding game. In the words of Peter Kaufman, it pays to “go positive and go first.” Also, remember that people make mistakes. Assuming there is no maliciousness, it pays to forgive.

This article is an excerpt from the bestselling book The Great Mental Models Volume 2: Physics, Chemistry and Biology

155. Chesterton's Fence: A Lesson in Second Order Thinking

A core component of making great decisions is understanding the rationale behind previous decisions. If we don't understand how we got "here," we run the risk of making things much worse.

When we seek to intervene in any system created by someone, it's not enough to view their decisions and choices simply as the consequences of first-order thinking because we can inadvertently create serious problems. Before changing anything, we should wonder whether they were using second-order thinking. Their reasons for making certain choices might be more complex than they seem at first. It's best to assume they knew things we don't or had experience we can't fathom, so we don't go for quick fixes and end up making things worse.

Second-order thinking is the practice of not just considering the consequences of our decisions but also the consequences of those consequences. Everyone can manage first-order thinking, which is just considering the immediate anticipated result of an action. It's simple and quick, usually requiring little effort. By comparison, second-order thinking is more complex and time-consuming. The fact that it is difficult and unusual is what makes the ability to do it such a powerful advantage.

Second-order thinking will get you extraordinary results, and so will learning to recognize when other people are using second-order thinking. To understand exactly why this is the case, let's consider Chesterton's Fence, described by G. K. Chesterton himself as follows: *There exists in such a case a certain institution or law; let us say, for the sake of simplicity, a fence or gate erected across a road. The more modern type of reformer goes gaily up to it and says, "I don't see the use of this; let us clear it away." To which the more intelligent type of reformer will do well to answer: "If you don't see the use of it, I certainly won't let you clear it away. Go away and think. Then, when you can come back and tell me that you do see the use of it, I may allow you to destroy it."*

Chesterton's Fence is a heuristic inspired by a quote from the writer and polymath G. K. Chesterton's 1929 book, *The Thing*. It's best known as being one of John F. Kennedy's favored sayings, as well as a principle Wikipedia encourages its editors to follow. In the book, Chesterton describes the classic case of the reformer who notices something, such as a fence, and fails to see the reason for its existence. However, before they decide to remove it, they must figure out why it exists in the first place. If they do not do this, they are likely to do more harm than good with its removal. In its most concise version, Chesterton's Fence states the following:

Do not remove a fence until you know why it was put up in the first place.

Chesterton went on to explain why this principle holds true, writing that fences don't grow out of the ground, nor do people build them in their sleep or during a fit of madness. He explained that fences are built by people who carefully planned them out and "had some reason for thinking [the fence] would be a good thing for somebody." Until we establish that reason, we have no business taking an ax to it. The reason might not be a good or relevant one; we just need to be aware of what the reason *is*. Otherwise, we may end up with unintended consequences: second- and third-order effects we don't want, spreading like ripples on a pond and causing damage for years.

Elsewhere, in his essay collection *Heretics*, Chesterton makes a similar point, detailed here:

Suppose that a great commotion arises in the street about something, let us say a lamp-post, which many influential persons desire to pull down. A grey-clad monk, who is the spirit of the Middle Ages, is approached upon the matter, and begins to say, in the arid manner of the Schoolmen, "Let us first of all consider, my brethren, the value of Light. If

Light be in itself good—” At this point he is somewhat excusably knocked down. All the people make a rush for the lamp-post, the lamp-post is down in ten minutes, and they go about congratulating each other on their un-mediaeval practicality. But as things go on they do not work out so easily. Some people have pulled the lamp-post down because they wanted the electric light; some because they wanted old iron; some because they wanted darkness, because their deeds were evil. Some thought it not enough of a lamp-post, some too much; some acted because they wanted to smash municipal machinery; some because they wanted to smash something. And there is war in the night, no man knowing whom he strikes. So, gradually and inevitably, to-day, to-morrow, or the next day, there comes back the conviction that the monk was right after all, and that all depends on what is the philosophy of Light. Only what we might have discussed under the gas-lamp, we now must discuss in the dark.

As simple as Chesterton’s Fence is as a principle, it teaches us an important lesson. Many of the problems we face in life occur when we intervene with systems without an awareness of what the consequences could be. We can easily forget that this applies to subtraction as much as to addition. If a fence exists, there is likely a reason for it. It may be an illogical or inconsequential reason, but it is a reason nonetheless.

“Before I built a wall I’d ask to know

What I was walling in or walling out,

And to whom I was like to give offence.”

— Robert Frost, “Mending Wall”

Chesterton also alluded to the all-too-common belief that previous generations were bumbling fools, stumbling around, constructing fences wherever they fancied. Should we fail to respect their judgement and not try to understand it, we run the risk of creating new, unexpected problems. By and large, people do not do things for no reason. We’re all lazy at heart. We don’t like to waste time and resources on useless fences. Not understanding something does not mean it must be pointless.

Take the case of supposedly hierarchy-free companies. Someone came along and figured that having management and an overall hierarchy is an imperfect system. It places additional stress on those at the bottom and can even be damaging to their health. It leaves room for abuse of power and manipulative company politics. It makes it unlikely that good ideas from those at the bottom will get listened to.

However, despite the numerous problems inherent in hierarchical companies, doing away with this structure altogether belies a lack of awareness of the reasons why it is so ubiquitous. Someone needs to make decisions and be held responsible for their consequences. During times of stress or disorganization, people naturally tend to look to leaders for direction. Without a formal hierarchy, people often form an invisible one, which is far more complex to navigate and can lead to the most charismatic or domineering individual taking control, rather than the most qualified.

It is certainly admirable that hierarchy-free companies are taking the enormous risk inherent in breaking the mold and trying something new. However, their approach ignores Chesterton’s Fence and doesn’t address why hierarchies exist within companies in the first place. Removing them does not necessarily lead to a fairer, more productive system. Yes, doing things the way they’ve always been done means getting what we’ve always got. There’s certainly nothing positive about being resistant to any change. Things become out

of date and redundant with time. Sometimes an outside perspective is ideal for shaking things up and finding new ways. Even so, we can't let ourselves be too overconfident about the redundancy of things we see as pointless.

Or, to paraphrase Rory Sutherland, the peacock's tail is not about efficiency. In fact, its whole value lies in its inefficiency. It signals a bird is healthy enough to waste energy growing it and has the strength to carry it around. Peahens use the tails of peacocks as guidance for choosing which mates are likely to have the best genes to pass on to their offspring. If an outside observer were to somehow swoop in and give peacocks regular, functional tails, it would be more energy efficient and practical, but it would deprive them of the ability to advertise their genetic potential.

All of us, at one point or another, make some attempt to change a habit to improve our lives. If you're engaging in a bad habit, it's admirable to try to eliminate it—except part of why many attempts to do so fail is that bad habits do not appear out of nowhere. No one wakes up one day and decides they want to start smoking or drinking every night or watching television until the early hours of the morning. Bad habits generally evolve to serve an unfulfilled need: connection, comfort, distraction, take your pick.

Attempting to remove the habit and leave everything else untouched does not eliminate the need and can simply lead to a replacement habit that might be just as harmful or even worse. Because of this, more successful approaches often involve replacing a bad habit with a good, benign, or less harmful one—or dealing with the underlying need. In other words, that fence went up for a reason, and it can't come down without something either taking its place or removing the need for it to be there in the first place.

To give a further example, in a classic post from 2009 on his website, serial entrepreneur Steve Blank gives an example of a decision he has repeatedly seen in startups. They grow to the point where it makes sense to hire a Chief Financial Officer. Eager to make an immediate difference, the new CFO starts looking for ways to cut costs so they can point to how they're saving the company money. They take a look at the free snacks and sodas offered to employees and calculate how much they cost per year—perhaps a few thousand dollars. It seems like a waste of money, so they decide to do away with free sodas or start charging a few cents for them. After all, they're paying people enough. They can buy their own sodas.

Blank writes that, in his experience, the outcome is always the same. The original employees who helped the company grow initially notice the change and realize things are not how they were before. Of course they can afford to buy their own sodas. But suddenly having to is just an unmissable sign that the company's culture is changing, which can be enough to prompt the most talented people to jump ship. Attempting to save a relatively small amount of money ends up costing far more in employee turnover. The new CFO didn't consider why that fence was up in the first place.

Chesterton's Fence is not an admonishment of anyone who tries to make improvements; it is a call to be aware of second-order thinking before intervening. It reminds us that we don't always know better than those who made decisions before us, and we can't see all the nuances to a situation until we're intimate with it. Unless we know why someone made a decision, we can't safely change it or conclude that they were wrong.

The first step before modifying an aspect of a system is to understand it. Observe it in full. Note how it interconnects with other aspects, including ones that might not be linked to you personally. Learn how it works, and *then* propose your change.

156. Multiplicative Systems: Understanding The Power of Multiplying by Zero

We all learned in math class that anything times zero is zero. But if you stop thinking about the idea here, you don't see all the practical applications that understanding multiplicative systems can give you in life.

Let's run through a little elementary algebra. Try to do it in your head: What's $1,506,789 \times 9,809 \times 5.56 \times 0$?

Hopefully, you didn't have to whip out the old TI-84 to solve that one. It's a zero.

This leads us to a mental model called Multiplicative Systems and understanding it can get to the heart of a lot of issues.

The Weakest Link in the Chain

Suppose you were trying to become the best basketball player in the world. You've got the following things going for you:

1. God-given talent. You're 6'9", quick, skillful, can leap out of the building, and have been the best player in a competitive city since you can remember.
2. Support. You live in a city that reveres basketball and you're raised by parents who care about your goals.
3. A proven track record. You were the player of the year in a very competitive Division 1 college conference.
4. A clear path forward. You're selected as the second overall pick in the NBA Draft by the Boston Celtics.

Sounds like you have a shot, right? As good as anyone could have, right? What would you put the odds at of this person becoming one of the better players in the world? Pretty high? Let's add one more piece of information:

5. You've developed a cocaine habit.

What are your odds now?

This little exercise isn't an academic one, it's the sad case of Leonard "Len" Bias, a young basketball prodigy who died of a cocaine overdose after being selected to play in the NBA for the Boston Celtics in 1986. Many call Bias the best basketball player who never played professionally.

What the story of Len Bias illustrates so well is the truth that anything times zero must still be zero, no matter how large the string of numbers preceding it. In some facets of life, all of your hard work, dedication to improvement, and good fortune may still be worth nothing if there is a weak link in the chain.

Something all engineers learn very early on is that a system is no stronger than its weakest component. Take, for example, the case of a nuclear power plant. We have a very good understanding of how to make the nuclear power plant quite safe, nearly indestructible, which it must be considering the magnitude of a failure.

But in reality, what is the weakest link in the chain for most nuclear power plants? *The human beings running them.* We're part of the system! And since we've yet to perfect the human being, we have yet to perfect the nuclear power plant. How could it be otherwise? An additive system does not work this way. In an additive system, each component adds on to one another to create the final outcome. Going back to algebra, let's say our equation was additive rather than

multiplicative: $1,506,789 \text{ plus } 9,809 \text{ plus } 5.56 \text{ plus } 0$. The answer is 1,516,603.56 — still a pretty big number!

Think of an additive system as something like a great Thanksgiving dinner. You've got a great turkey, some whipped potatoes, a mass of stuffing, and a lump of homemade cranberry sauce, and you're hanging with your family. Awesome!

Let's say the potatoes get burnt in the oven, and they're inedible. Problem? Sure, but dinner still works out just fine. Someone shows up with a pie for dessert? Great! But it won't change the dinner all that much.

The interaction of the parts makes the dinner range from good to great. Take some parts away or add new ones in, and you get a different outcome, but not a *binary*, win/lose one. The meal still happens. Additive systems and multiplicative systems react differently when components are added or taken away.

Most businesses, for example, operate in a multiplicative system. But they too often *think* they're operating in additive ones: Ever notice how some businesses will add one feature on top of another to their products but fail at basic customer service, so you leave, never to return? That's a business that thinks it's in an additive system when they really need to be resolving the big fat *zero* in the middle of the equation instead of adding more stuff.

Financial systems are, of course, multiplicative. General Motors, founded in 1908 by William Durant and C.S. Mott, came to dominate the American car market to the tune of 50% market share through a series of brilliant innovations and management practices and was for many years the dominant and most admirable corporation in America. Even today, after more than a century of competition, no American carmaker produces more automobiles than General Motors.

And yet, the original shareholders of GM ended up with a *zero* in 2008 as the company went into bankruptcy due to years of financial mismanagement. It didn't matter that they had several generations of leadership: All of that becomes naught in a multiplicative system.

On a smaller scale, take the case of a young corporate climber who feels they just can't get ahead. They seem to have all their ducks in a row: great resume, great background, great experience...the problem is that they suck at dealing with other people and treat others like stepping stones. That's a *zero* that can negate *all* of the big numbers preceding it. The rest doesn't matter.

And so we arrive at the "must be true" conclusion that understanding when you're in an additive system versus a multiplicative system, and which components need absolute reliability for the system to work, is a critical model to have in your head. Multiplicative thinking is a model related to the greater idea of systems thinking, another mental model well worth acquiring.

157. 349 mental models

Mental Models in Economics and Strategy

Opportunity Cost

The value of what you have to give up in order to choose something else. As with any other cost, the goal is to minimize it. Opportunity costs are very real.

A central component of economics is the time value of money which means that money today is worth more than money in the future. Economically, this relationship is entirely based on opportunity costs.

Creative Destruction

Sometimes called Schumpeter's gale and formulated after Austrian economist Joseph Schumpeter, creative destruction is a theory of economic innovation and the business cycle in a free-market economy. It refers to the incessant product and process innovation mechanism by which new production units replace outdated ones – or ones stuck without innovation.

In capitalistic competition, the absence of innovation does not result in stasis. It results in decay.

Primary source: Joseph Schumpeter

Double-Entry Bookkeeping

The invention of the double-entry bookkeeping system traces all the way to Genoa in 1494 when the first book on the subject was published by Luca Pacioli. Ever since then, the system of balancing the books by using two accounts for every entry has hardly changed. The duality that is an essential part of an accountant's view of the world is a remarkably powerful model for understanding economic and other events.

Primary source: Luca Pacioli

Comparative Advantage

As a foundational model in the theory of international trade, Scottish economist David Ricardo found that all actors, at all times, can mutually benefit from cooperation and voluntary trade if those actors focus on what they are comparatively best at in terms of opportunity cost.

The party with the lower opportunity cost of producing a good or service, and thus the smallest potential lost benefit, holds the comparative advantage of that good or service.

Primary source: David Ricardo

Rent-Seeking

An attempt to make a profit (economic rent) at the expense of others rather than by creating new value. An example is using resources on political lobbying to promote specific legislation that serves one's own interests.

Primary source: David Ricardo

Switching Cost

The transaction costs or disadvantages a buyer incurs from switching to another seller.

Nash Equilibrium

When two or more participants in a non-cooperative game have no incentive to deviate from their respective equilibrium strategies after considering their opponent's choices and strategies on a rational basis.

Named after mathematician John Nash, the model proves that decisions that are good for individuals can sometimes be terrible for groups.

Primary source: John Nash

AD-AS Model

Based on John Maynard Keynes's general theory, the AD-AS model explains the level of prices and national income through the relationship of aggregate demand and aggregate supply. Being a fundamental tool in economics, it's an incredibly powerful model when thinking about macroeconomic effects in the short, medium, and long term.

The model is flexible enough to accommodate both Keynes's law approach, which focuses on aggregate demand and the short run, while also including Say's law approach, which focuses on aggregate supply and the long run.

Controlling the Center

Controlling the center of something provides greater flexibility and mobility of choices compared to one's competitor. In chess, if you don't control the center squares and let your opponent control them, they will have an easier game than if they have to fight for their control. A piece does not have to physically be on a central square to control the center. For example, the bishop can control the center from afar.

In business, controlling the center of a value chain can prove mightily profitable. Examples include the business model of brokerage firms or indispensable internet marketplaces such as Alibaba.

Specialization

Sometimes termed division of labor, specialization refers to the process by which participants in a free-market system divide into different sets of skills to increase efficiency. By increasing productivity within each field of specialization, the whole system benefits.

Primary source: Adam Smith

Intellectual Property

The introduction of intellectual property rights into society has been a huge accelerator of societal creativity. Such rights include intangible creations of the human intellect. There are many types of them, and some countries recognize more than others. The most well-known are copyrights, patents, trademarks, and trade secrets. If individuals and corporations get these right, they can create defensible economic moats against the competition. And as long as ongoing research and development and capital expenditures can be managed, there is tremendous leverage in this model.

However, very few, if any, economic moats originating from intellectual property seem to be able to stand the test of time. Either they're expiring or becoming obsolete due to societal progress and creative destruction. But they can last for very long.

Utility

The concept used to assess how satisfaction levels affect consumer decisions. The law of diminishing marginal utility describes how the initial units of a good or service carry more utility than each additional unit.

The concept has its roots from the 19th century as economists worked on explaining price discovery. This mechanism was originally thought to be solely driven by a product's utility. Adam Smith then proposed the problem known as "the paradox of water and diamonds" which made it very difficult to explain why diamonds should be valued more highly than an essential good such as water.

That was until the discovery was made to explain that economic decisions are made based on marginal benefit rather than total benefit. In other words, consumers are not choosing between all the diamonds in the world vs. all the water in the world. Clearly, water is more valuable. Instead, they are choosing between one additional diamond versus one additional unit of water.

Primary source: John Stuart Mill

Elasticity

The economic measure of how responsive an economic variable, such as demand, is to a change in another, such as price. An elastic variable has an absolute elasticity value greater than 1 and responds more than proportionally to changes in the dependent variable. An inelastic variable has an absolute elasticity value less than 1 and changes less than proportionally to changes in the dependent variable.

Supply and Demand

Being the main model of price determination used in economic theory, the supply and demand relationship explains a lot of things in the world. The basic premise is that prices settle at equilibrium when demand equals supply.

While it's easy to take the model of supply and demand for what it is, it's important to know that there are blind spots. In some situations, the model is not as rigid as economics presumes when seen in the context of behavioral psychology, incentives, contrast, etc. As Charlie Munger puts it: Suppose that you raise the price and use the extra money to bribe the other guy's purchasing agent.

Deadweight Loss

A loss of economic efficiency that is caused by supply and demand being out of equilibrium. Such causes may include price and rent controls, minimum wages, taxation, and monopolies.

Moral Hazard

A situation where either party to an entered agreement changes its behavior after the contract is completed so that the probabilities attributed to either party's way of acting no longer apply. It's called moral hazard because the party is no longer fully affected by the negative effects of its own actions. Thus, it might be incentivized to act less cautiously than otherwise.

Bottlenecks

Matter, either tangible or intangible, can get clogged if pushed too quickly through a system than what that system can handle. Every system is limited by various constraints with some critical and some less critical. No change to the system will result in overall improvement unless that change addresses the bottleneck. The term is named after the narrow point of a typical bottle.

Bribery

Bribery is a form of a moral-breaking bottleneck in human systems which is hard to eliminate. The concept can in some circumstances significantly affect other models such as price discovery, incentive-induced bias, and so on.

Arbitrage

The attempt to profit by exploiting price differences in identical or similar financial instruments, capitalizing on the imbalance. As more and more arbitrageurs participate, such opportunities diminish and eventually vanish. The traditional definition of arbitrage concerns a 100% risk-free activity after transaction costs. But in practice, that is rarely certain.

Scarcity

Limited availability of something gives rise to trade-off. Rarely is something of limitless supply, except maybe the need for it. Scarcity involves making a sacrifice by giving something up—or making a trade-off—in order to obtain more of the scarce resource that is wanted.

Mr. Market

Benjamin Graham proposed imagining the stock market as a somewhat manic and not too intelligent profile who would stop by every day to call out prices. Mr. Market will not care if you are interested but will show up every day. However, his mood is subject to extreme changes. There will be times when he is optimistic about the future and so his prices will be high. There will be times when he is pessimistic about the future and so his prices will be low. For the most part, it's best to ignore his shouting. But when Mr. Market becomes extremely worked up—either excited or depressed—you can exploit his out-of-boundary prices.

The model of Mr. Market is simple, but here's the problem: it sounds easy to put into practice. But the truth of the matter is that there's a collective mass of real people on the other side of every transaction. This group might be better educated, have more capital, have more power, and have more experience. So after a while, one might feel that Mr. Market and these people are all superior.

But even then, the model of Mr. Market is paramount.

Primary source: Benjamin Graham

Fisher Effect

A direct relation to the concept of money neutrality, named after economist Irving Fisher. The Fisher effect states that the real rate of interest in an economy is stable over time so that changes in nominal interest rates are the result of changes in expected inflation. Therefore, the nominal interest rate in an economy is the sum of the required real rate of interest and the expected rate of inflation over any given time horizon.

Primary source: Irving Fisher

Cancer Surgery Formula

Charlie Munger explains: I've had many friends in the sick-business-fix-up-game over a long lifetime. And they practically all use the following formula — I call it the cancer surgery formula: They look at this mess and they figure out if there's anything sound left that can live on its own if they cut away everything else. And if they find anything sound, they just cut away everything else. Of course, if that doesn't work, they liquidate the business. But it frequently does work.

Primary source: Charlie Munger

Surfing

You won't be able to surf if you don't catch the wave. And if you do catch it, you can stay on it for long. The trick is catching the one that lasts the longest as early as possible and not to get off. Microsoft was a result of a 16-year-old catching a wave of software revolution right on the edge.

Primary source: Charlie Munger

Porter's Five Forces

Developed by Michael Porter in 1979, Porter's Five Forces is a framework to look at competitive forces in an industry. The five undeniable forces are: 1) threat of new entrants, 2) threat of substitutes, 3) bargaining power of customers, 4) bargaining power of suppliers, and 5) competitive rivalry.

Primary source: Michael Porter

Phillips Curve

A historical inverse relationship between rates of unemployment and corresponding rates of rises in wages that result within an economy.

Primary source: Williams Phillips

Parity Conditions

Where two (or more) things are equal to each other. In economics, this might include equality in price, rate of exchange, purchasing power, or wages. Parity conditions typically make simplifying assumptions, such as zero transaction costs, perfect information that is available to all market participants, risk neutrality, and freely adjustable market prices.

International exchange rate parity conditions:

1. Covered interest rate parity
2. Uncovered interest rate parity
3. Forward rate parity
4. Purchasing power parity
5. International Fisher effect.

The covered interest rate parity is the only parity condition that is enforced by arbitrage.

Transaction Costs

Transaction costs can essentially be divided into three broad categories:

1. Search and information costs are costs associated with determining whether the desired good is available in the market, where the lowest price exists, and so on.
2. Bargaining and decisions costs are costs used to reach an acceptable agreement with the counterparty in the transaction, write an appropriate contract, and so on. In asset markets and in market microstructure, the transaction cost is some function of the distance between the bid and ask.
3. Policing and enforcement costs are costs incurred to ensure that the counterparty complies with the agreement or to respond appropriately (often through the judicial system) if it proves that the counterparty doesn't.

Founder's Syndrome

The situation where leaders of companies are so emotionally invested in them that they can't effectively delegate decisions, leading to micromanagement and stasis.

Luxury Paradox

More expensive goods are less likely to be used regularly than cheaper alternatives even though the higher price might indicate higher quality. The relationship between price and utility is an inverted U.

Winner's Curse

In open cry auctions and bidding wars, the winning bid has a tendency to exceed the intrinsic value of the item won. The smartest side to take in a bidding war is the losing side.

Ratchet Effect

During times of crisis, government spending increases but has a tendency to not fall back to pre-crisis levels when the crisis is over.

Primary source: Alan Peacock; Jack Wiseman

Iron Law of Civilization 3.0

A freely competitive market is a mechanism that is constantly self-evolving, self-advancing, and self-perfecting. When there is more than one market, the largest will eventually become the only one, since if any individual, society, enterprise, or nation is removed from this single market, it will start to steadily fall behind and will ultimately be forced to join in. So, the best way for any nation to build its own strength is to abandon all trade barriers and join the largest international free market system in the world. The best way to fall behind is to close itself off from other countries.

Primary source: Li Lu

Say's Law

According to Say's law, supply creates demand because the income generated by past production and sale of goods is the source of spending that creates the demand to purchase current production. The reasoning is that to have the means to buy, a buyer must first have produced something to sell. And thus, the source of demand is production itself. As actor Kevin Costner says in the movie, Field of Dreams: If you build it, he will come.

Primary source: Jean-Baptiste Say

Paradox of Choice

The effect of how eliminating consumer choices can greatly reduce anxiety for users. There are, however, certain limitations about this paradox. Should there then be no choice at all? And if that be the case, how would business look like? If so, would all industries operating in an oligopoly switch to a monopoly leading to higher prices?

Primary source: Barry Schwartz

Hick's Law

Related to the paradox of choice, Hick's law poses that increasing the number of choices will increase decision time logarithmically. The more choices presented to users, the longer it will take them to reach a decision but the marginal decision time per extra choice decreases.

Primary source: William Edmund Hick

Free Rider Problem

A form of market failure where those who benefit from resources, goods, or services do not pay for them, which results in an under-provision of those goods or services. If someone builds a lighthouse, all sailors will benefit from its illumination.

When people are asked how much they value a particular public good, with that value measured in terms of how much money they would be willing to pay, their tendency is to under-report their valuations.

Cockroach Theory

When bad news is revealed, there may be many more related negative events yet to be revealed. There's never just one cockroach in the kitchen.

Evolutionary Stable Strategy

A subject in game theory indicating a strategy that is impenetrable by competitors once initiated. The evolutionary stable strategy creates a form of Nash equilibrium that is "evolutionarily" stable: once it is fixed in a population, natural selection alone is sufficient to prevent alternative strategies from successfully invading.

Two conditions must be present for such a circumstance:

1. The entity employing the strategy must be better than any other entity that employs the same strategy or any other strategy
2. Should a new strategy evolve that is equally as good, the entity employing the original strategy must do better than any entity employing both strategies.

Primary source: John Maynard Smith

Unknown Unknowns

Known unknowns are risks one is aware of, such as canceled flights or worker injuries.

Unknown unknowns are risks coming from situations that are so out of this world that they are not imagined in advance.

Critical Mass

A term borrowed from physics, critical mass is the minimum amount of something required to sustain itself going forward. In the scene of social networks, critical mass refers to the number of adopters for a system that is required for the further adoption rate to be self-sustaining. In nuclear physics, it's the smallest amount of fissile material needed for a sustained nuclear chain reaction.

Freemium

A pricing strategy by which a good or service is offered for free to spur the growth of adoption but with a price charged for proprietary features or functionality. The business strategy has been used in the software industry since the 1980s.

Crowdsourcing

A sourcing model for soliciting ideas or finances from a large group of participants rather than from employees or suppliers. It's a method of "outsourcing work to the crowd".

Diversification

When multiple uncorrelated subjects move with certain volatilities, splitting the interest between them produces collective volatility which is lower than either of those subjects' volatilities. The strategy of diversification is commonly used in portfolio management by allocating capital to a mix of different investments with the ultimate goal of reducing volatility.

3-6-3 Rule

The value of a bank is easier to value based on how efficiently it utilizes the 3-6-3 rule which goes like this: a bank pays 3% on savings accounts, loans out money to businesses with solid financials at 6%, and then the banker leaves the office at 3 p.m. to play golf. Excessive presence of derivatives on a bank's books undermines the 3-6-3 rule.

First-Mover and Last-Mover Advantage

The advantage gained by the initial significant occupant of a market. First-mover advantage may be gained by technological leadership or early purchase of resources. However, in certain growth markets, the last-mover might be better positioned competitively if it's able to introduce the last great development in that market to gain years of monopoly profits.

Related to inversion, Grandmaster chess player José Raúl Capablanca said: You must study the endgame before everything else.

Principal-Agent Problem

The theory of delegation and accountability between individuals used in many areas of social sciences, but primarily political science and economics.

The theory deals with relationships where one party (the principal) delegates the performance of a given task to another party (the agent). The principal wants the agent to perform the task satisfactorily, but the principal has a problem that consists in establishing a payment structure – a reward – that gives the agent sufficient incentive to perform the task in accordance with the principal's wishes.

Principal-agent problems are a frequent cause of market failure.

Market for Lemons Problem

The quality of goods traded in a market can degrade in the presence of information asymmetry between buyers and sellers, leaving only "lemons" behind – e.g. a car that is found to be defective after purchase.

Primary source: George Akerlof

Minsky Moment

A sudden collapse of asset values marking the end of a credit cycle or an economic cycle.

Primary source: Hyman Minsky

Zero to One Theory

A thought experiment by Peter Thiel stating that technology and globalization are different modes of progress. Globalization is horizontal progress that goes from 0 to n while technology is vertical and goes from 0 to 1.

Primary source: Peter Thiel

Winner's and Loser's Games

Any game should either be played as a Winner's Game or a Loser's Game.

Winner's Games are ones in which the outcome of the game is entirely dependent on the player's ability, such as chess or sprinting.

Loser's Games are ones in which the players struggle to compete against *the game itself*. In Loser's Games you make more progress getting ahead by avoiding mistakes rather than making brilliant decisions.

What's important is whether you can assess which one you are dealing with and adjust your winning strategy accordingly.

Primary source: Simon Ramo

Exit, Voice, and Loyalty Model

A model used in assessing how a negative change to an agent's environment by another agents affects their actions. Commonly used in political science and organizational behavior, the model essentially proposes that agents have two possible responses to a negative outside effect: they can either *exit* (withdraw from the relationship) or they can *voice* (attempt to repair or improve the relationship).

Primary source: Albert Hirschman

Lucas Critique

It is naive to try to predict the effects of a change in economic policy entirely on the basis of relationships observed in historical data, especially highly aggregated historical data

Primary source: Robert Lucas

Mental Models in Human Nature and Judgment

Trust

Trust is a fundamental part of human nature and is pretty much all-encompassing in all we do. Trust produces increased speed, efficiency, empower ethical decision making, and hence, decreases costs.

Availability Heuristic

The tendency to judge the frequency of events in the world by the ease with which examples come to mind. We tend to most easily recall what is salient, important, frequent, and recent. So, we make decisions based on what we most easily recall but this undermines our ability to accurately judge frequency and magnitude.

Primary source: Daniel Kahneman; Amos Tversky

Anchoring

The tendency to rely too much on an initial piece of information when making subsequent judgments. The cognitive bias of anchoring is closely related to availability heuristic since the mind anchors to what information is familiar.

Primary source: Daniel Kahneman; Amos Tversky

Reciprocity

A social norm of responding to a positive action with another positive action, even if the action received has been unwanted. The interesting thing is that the positive action returned is oftentimes bigger than the initial action received.

Primary source: Robert Cialdini

Envy and Jealousy

Trying to avoid envy in an interconnected world is very difficult. It's a phenomenon that lies deep in human nature going back to ancient times. The Stoics warned against the consequences of envy, but yet it's still ingrained in human nature as ever. Warren Buffett says: It is not greed that drives the world, but envy.

Denial

Denial is a powerful psychological effect. When reality is too painful to bear, denial just distorts it until it's bearable. The refusal to accept reality or fact is a primitive defense or survival mechanism.

Stress

A situation that triggers a particular biological response when perceiving threat or standing in front of a major challenge. Stress triggers your fight-or-flight response and traces all the way back to assisting hunter-gatherer ancestors to survive.

Yerkes-Dodson law states that performance increases with anxiety and excitement, but only to a point.

Social Proof

In a study, researchers arranged for a man to violate the law by crossing the street against red light right into traffic. In half the instances, he was dressed in a business suit and tie. In the other half, he wore a work shirt and trousers. The study showed that three times as many pedestrians were swept along behind the man into traffic, against the light, and against the law, when he wore a suit.

Social proof, coined by Robert Cialdini, is a powerful psychological phenomenon of assuming the actions of others in an attempt to reflect correct behavior for a given situation.

Primary source: Robert Cialdini

Framing

The way a question or situation is framed can determine your response and lead to an action decided based on whether the options are presented with positive or negative connotations. Mixed with the narrative fallacy, framing can turn out dangerous for errors in decision making and might be used as power over others' behavior.

Primary source: Daniel Kahneman; Amos Tversky

Mental Accounting

A tendency to divide money into different pots and then treat them all separately based on subjective criteria. According to Richard Thaler, people think of value in relative rather than absolute terms. They derive pleasure not just from an object's value, but also the quality of the deal – its transaction utility. The phenomenon helps explain why people are willing to spend more when they pay with a credit card than cash.

Primary source: Richard Thaler

Pavlovian Association

Ivan Pavlov's learning procedure of pairing a stimulus with a conditioned response. The idea emerged from an experiment on Pavlov's dogs demonstrating how the ring of a bell and the presence of a bowl of dog food (stimulus) would trigger an unconditioned response (salivation). Pavlov also came to notice that his dogs started to associate his lab assistant with food, creating a learned and conditioned response.

Primary source: Ivan Pavlov

Operant Conditioning

A method of learning through rewards and punishment. Such methods take place in many natural settings as well as in more structured settings such as the classroom or therapy sessions.

Primary source: B. F. Skinner

Commitment and Consistency Bias

A tendency to want to be consistent with one's prior actions. Because human actions, beliefs, and commitments help form self-perception, the commitment and consistency bias creates a reluctance to change a course of action once it's chosen even though that action may be forced by someone else.

Primary source: Robert Cialdini

Sunk Cost Fallacy

Linked to anchoring bias and commitment bias, the sunk cost fallacy is the tendency to continue an endeavor due to resources and effort invested in that endeavor even though cutting it loose seems to be a wise choice. Research suggests that rats, mice, and humans are all sensitive to sunk costs after they have made the decision to pursue a specific reward.

Liking Tendency

As Robert Cialdini puts it: It's no surprise that people prefer to say yes to a request to the degree that they know and like the requester. A simple way to make things happen in your direction is to uncover genuine similarities or parallels that exist between you and the person you want to influence, and then raise them to the surface. That increases rapport.

Primary source: Robert Cialdini

Stereotyping

A tendency to over-generalize a population or class of people. The concept is closely related to the availability heuristic.

Groupthink

The strive and desire for harmony, conformity, and compromise in a group can result in an irrational or dysfunctional decision-making outcome, although the opposite might be the purpose of creating the group.

Primary source: William H. Whyte Jr.

Authority Bias

The behavioral tendency to attribute greater weight and accuracy to the opinion of someone with an authority. This sometimes happens even when an individual believes that there's something wrong with following the authority, and even when there wouldn't be a penalty for defying them.

In 1961, the now-famous Milgram experiment was conducted by Stanley Milgram, a professor of psychology at Yale University. In it, participants were ordered to administer painful and potentially harmful electric shocks to another person they could not see. Many of them did so, even when they felt that it was wrong, and even when they wanted to stop because they felt pressured by the perceived authority of the person leading the experiment.

Primary source: Stanley Milgram

First-Conclusion Bias

A tendency to settle on the first information or conclusion adopted for a given problem, thus remaining resistant to the search for any more alternatives.

Confirmation Bias

The tendency to interpret a situation or seek out reinforcing evidence according to pre-existing beliefs. Charles Darwin is said to not have been able to come up with the theory of evolution without applying a constant process of destroying confirmation bias in his studies. He constantly sought out and noted observations that were opposed to what he thought and made an intense effort to investigate them.

Hindsight Bias

Also called creeping determinism, it's the tendency of overestimating one's ability to have predicted an outcome that could not possibly have been predicted. Hindsight bias is dangerous because it hinders one from learning from past mistakes. If we feel like we knew it all along, it means we won't stop to examine why something really happened.

Recommended reading: [Looking Back at 2020 \(in Hindsight\)](#)

Survivorship Bias

A form of selection bias where the survivors—or the illuminated data—of a particular subject are disproportionately evaluated.

A commonly held belief is that machinery, equipment, and goods manufactured in previous generations often is better built and last longer than comparable items built during present times. You usually hear someone say: They don't make 'em like they used to. But because of the selective pressures of time and usage, it is inevitable that only those items which were built to last will have survived into the present day.

Curse of Knowledge

Once we learn something, we find it hard to imagine what it was like not to know it and thus find it difficult to think about problems from the perspective of lesser-informed people. The more knowledgeable you became on a subject, the more unnatural it becomes to communicate that idea in a simple and clear way. In short, knowledge itself becomes a barrier to its own propagation.

Primary source: Colin Camerer; George Loewenstein; Martin Weber

Reductive Bias

The need to treat non-linear complex systems as if they are linear. Mistakes generally arise from the mismatch between the complex reality one faces and the simplifying mental routines one uses to cope with that complexity.

Incentive-Caused Bias

People do what they're incentivized to do. If someone is paying someone to be irresponsible, that someone is likely to be irresponsible. You generally get the outcome that you reward for. So you need to be very careful about how you design those rewards.

Representativeness Heuristic

Consider the following: Linda is 31, bright, single, and outspoken. She majored in philosophy at the university. As a student, she was deeply concerned with issues of discrimination and social injustice, and also participated in antinuclear demonstrations. Is it more likely that Laura works at a bank? Or, is it more likely that she works at a bank and is active in the feminist movement?

Opting for the last option is prone to representativeness heuristic—the tendency to let the similarity of objects or events confuse one's thinking about the probability of an outcome. Because the possibility that Linda is active in the feminist movement is a subset of a more inclusive category, the probability of her just working at a bank is simply higher.

Primary source: Daniel Kahneman; Amos Tversky

Narrative Instinct

Because we have a strong tendency to make sense from cause-and-effect, stories help us make sense of the world and are therefore remarkably powerful. But you could imagine the kinds of tripwires of errors this might cause. Just think back to the story of Linda in the prior model of representativeness heuristics.

Bizareness Effect

Bizarre or controversial information is easier to recall than what is common.

Baader-Meinhof Phenomenon

Also known as a frequency illusion, this phenomenon is an illusion where once something has recently come to one's attention, it suddenly seems to appear with improbable frequency shortly afterward, making one overestimate its prevalence. Closely related to selection and recency bias.

Cobra Effect

At the time of British rule of colonial India, the British government was concerned about the number of venomous cobra snakes in Delhi and so it offered a bounty for every dead cobra. The policy initially appeared successful. Eventually, however, the number of dead cobras being presented for bounty payment began to increase over time and it was discovered that people began to breed cobras for the income. When the government became aware of this, the reward program was scrapped, causing the cobra breeders to set the now-worthless snakes free. As a result, the wild cobra population further increased. The apparent solution to the problem made the situation even worse.

Hence, the Cobra effect is when an attempted solution to a problem makes the very problem worse. The root of the cause is often applying too linear thinking to the problem while neglecting the effect of feedback loops. The model shows that simplistic policies can come back to bite you.

Boomerang Effect

An unintended consequence of people being persuaded to do one thing but then turning around to the opposite. Sometimes referred to as the theory of psychological reactance, the boomerang effect basically occurs when individuals perceive that someone attempts to restrict their freedom.

Curiosity Instinct

Curiosity opens up for exploration, investigation, and learning. Without the human curiosity instinct, science and technology would not be present. Companies do not survive without curiosity.

Language Instinct

Humans are born with an innate capacity for language and this capacity shows a lot about our cognitive organization. Steven Pinker sees language as an ability unique to humans, produced by evolution to solve the specific problem of communication among social hunter-gatherers.

Primary source: Steven Pinker

Hasty Generalization

Closely related to stereotyping, the human mind tends to generalize based on general rules from a sample set of data. But sometimes when the data does not fit the population, it leads to overgeneralization. As Daniel Kahneman puts it: Extreme outcomes (both high and low) are more likely to be found in small than in large samples. This explanation is not causal.

Relative Satisfaction

The tendency to determine one's own level of satisfaction by comparing circumstances to others' circumstances. Envy and jealousy are strongly caused by relative satisfaction. As Charlie Munger said: Envy is a really stupid sin because it's the only one you could never possibly have any fun at.

Kantian Fairness Tendency

Emmanuel Kant's ethical theory of fairness requires that, for an action to be permissible, it must be possible to apply it to all people without a contradiction occurring.

The human psyche is strongly tended towards the idea of fairness. But life isn't fair and many can't accept this. Tolerating a little unfairness should be okay if it means greater fairness for all. We want things to balance but balance is not the order of life.

Fundamental Attribution Error

The tendency to overemphasize personal characteristics and ignore situational factors when judging others' actions and behavior. It results in believing that what people do reflects who they are.

Consider the case where Alice, a driver, is cut off in traffic by Bob. Alice instantly attributes Bob's behavior to his fundamental personality, e.g. that he's selfish and an unskilled driver. She does not immediately consider that Bob might be late for a flight, his son's birth, or an accident. Inversely, Alice might well make the opposite mistake and excuse herself by saying she herself was influenced by situational causes. Also termed the actor-observer symmetry.

Primary source: Lee Ross

Action Bias

Waiting and watching is torture, so humans have a tendency to act even when no action is needed. The best decision is sometimes to watch the grass grow.

Principle of Least Effort

A theory postulating that animals, humans, and well-designed machines will naturally seek the path of least resistance, and that effort declines as the minimum acceptable result is attained.

Primary source: Guillaume Ferrero

Cognitive Dissonance

The effect of simultaneously trying to believe two incompatible things at the same time. When people smoke even though they know it's pretty bad for them, they experience cognitive dissonance.

Primary source: Leon Festinger

Hard-Easy Effect

We tend to overestimate our ability to do something hard and underestimate our ability to do something easy. And so we attempt to focus on what's hard even though the thing that's easy might bring the same, or larger, rewards. Related to the Dunning-Kruger effect.

Primary source: Leon Festinger

Focusing Effect

The tendency to put too much emphasis on limited factors that do not matter much as part of a larger system. In other words, it's when someone doesn't see the forest for the trees. Daniel Kahneman once said: Nothing in life is as important as you think it is, while you are thinking about it.

Recency

The tendency to weigh recent information more heavily because that information seems more vivid even though it might be less important than past information. It's closely related to the availability heuristic.

Planning Fallacy

Tasks often take longer than expected. First proposed by Daniel Kahneman and Amos Tversky in 1979, the planning fallacy is an effect of optimism bias and is describing not only the underestimation of time but also of costs and risks.

Primary source: Daniel Kahneman; Amos Tversky

Reputation Fragility

As Warren Buffett says: It takes 20 years to build a reputation and 5 minutes to ruin it.

Noise Bottleneck

Coined by Nassim Taleb, a noise bottleneck is when more sampling of something decreases the signal-to-noise relation, increasing the amount of randomness, and decreasing the probability of sound conclusions. We tend to think that consuming more information is better except when that causes us to place too much emphasis on irrelevant data.

Primary source: Nassim Taleb

Keynesian Beauty Contest

Closely related to the pari-mutuel system, a Keynesian beauty contest is a concept used to describe an action that is based not on one's own perception but an inference of what one thinks the public perception will be of a subject. This can be carried one step further to take into account the fact that other entrants would each have their own opinion of what public perceptions are. Thus, the strategy can be extended to the next order and the next, and so on, at each level attempting to predict the eventual outcome of the process based on the reasoning of other rational agents.

To demonstrate this, John Maynard Keynes used an analogy based on a fictional newspaper contest in which contestants were asked to choose the six most attractive faces from a hundred photographs. Those who picked the most popular faces would win a prize.

Keynes then argued: It is not a case of choosing those [faces] that, to the best of one's judgment, are really the prettiest, nor even those that average opinion genuinely thinks the prettiest. We have reached the third degree where we devote our intelligences to anticipating what average opinion expects the average opinion to be. And there are some, I believe, who practice the fourth, fifth, and higher degrees.

Primary source: John Maynard Keynes

Serpico Effect

Named after Frank Serpico, who became known for whistleblowing on police corruption in the late 1960s and early 1970s, the Serpico effect is the tendency to rationalize an action because everyone else is doing it.

Depressive Realism

A hypothesis stating that depressed people make more realistic inferences than non-depressed people. It's the opposite of being blissfully unaware. While a useful mental model, the evidence for depressive realism is largely debated and remains a hypothesis.

Primary source: Lauren Alloy; Lyn Yvonne Abramson

Skill Compensation

People who are relatively good at one thing might tend to be relatively poor at another. An effect of trade-offs in deciding the time spent developing one skill over another.

Compassion Face

The tendency to have more compassion for victims within small groups than larger groups, because the smaller the group the easier it is to identify individual victims. One victim can break our hearts while larger groups seem more distanced.

Three Men Make a Tiger

A Chinese proverb that underlines the tendency to accept absurd information as long as it is repeated enough times by enough people. If one person tells you there's a tiger roaming around town, you might assume they're lying. If two people tell you, you begin to wonder. If three say it's true, you're getting closer to believing it.

Primary source: Pang Cong

Buridan's Ass

Coined after French philosopher Jean Buridan, Buridan's ass is a type of decision paralysis where two equally good options lead to no decision.

The paradox is explained by the story of a donkey that is equally hungry and thirsty and placed precisely midway between a stack of hay and a pail of water. Since the paradox assumes the donkey will always go to whichever option is closer, it dies of both hunger and thirst since it cannot make any rational decision between its two options.

Primary source: Jean Buridan

Imposter Syndrome

The fear of being exposed as less talented than one's surroundings think about one. Also termed impostorism, the phenomenon occurs when individuals feel they do not deserve all they have achieved.

Primary source: Pauline R. Clance; Suzanne A. Imes

Semmelweis Effect

Related to first-conclusion bias, the Semmelweis reflex is the tendency to reject new evidence or new information because it contradicts established norms, beliefs, or paradigms. It's named after a Hungarian doctor named Ignaz Semmelweis who discovered that patients treated by doctors who wash their hands get fewer infections but struggled to convince others that his finding was true.

Primary source: Ignaz Semmelweis

False-Consensus Effect

The tendency to erroneously believe that your views or beliefs are more widely held within a population than they are. This false consensus increases or decreases self-esteem, overconfidence effect, or a belief that everyone knows one's own knowledge. Relation to the curse of knowledge.

McNamara Fallacy

Named after Robert McNamara, the US Secretary of Defense during the Vietnam War, it's the belief that rational decisions are made solely on the basis of quantitative evidence, ignoring all other factors. McNamara measured success during the war solely on the measure of enemy body counts, causing the US army to lose track of the war's strategic objectives. Don't presume that what can't be measured isn't really important.

Courtesy Bias

The resistance to giving an honest opinion due to a desire not to offend the person or organization responding to. A frequent example is of employees hesitant to giving an honest opinion to their superiors, clogging information flow for rational decision making in the company.

Lucid Fallacy

Identified by Nassim Taleb and described in *The Black Swan*, the ludic fallacy is the tendency to falsely associate simulations with real life. Because simulations are designed as "narrow worlds of game and dice", they fail to account for chaos regarding future events in the real world.

Primary source: Nassim Taleb

Dunning-Kruger Effect

The cognitive bias that can be observed when people with beginning-level competencies tend to overestimate their own abilities. The effect, documented by and named after psychologists David Dunning and Justin Kruger, is explained by the fact that at this level of understanding and competence, one has not yet learned to recognize the limits of one's own competencies. Knowing the limits of one's intelligence requires a certain level of intelligence.

Primary source: David Dunning; Justin Kruger

Abilene Paradox

The situation where a group decides to make a decision that is counter to the thoughts and feelings of its individual members in the group. It happens because the members fail to communicate their individual beliefs.

Primary source: Jerry B. Harvey

In-Group Favoritism

Related to the liking tendency, in-group favoritism is the inclination to give preference to people within your own social group. Nepotism is an example.

Primary source: William Sumner

Collective Narcissism

The tendency to exaggerate the positive image and importance of a group that one belongs to.

Primary source: Sigmund Freud

Normalcy Bias

The tendency to believe threats and disasters are not at all probable due to a belief that things will remain as they always have.

Texas Sharpshooter Fallacy

The action of picking the target to go for after making the shot, making it impossible to miss. When the same data is used both to construct and test a hypothesis, conclusions are misguided.

Plain Folks Fallacy

A logical fallacy involving speakers attempting to convince an audience that they, and their ideas, are “of the people” and that they themselves are Average Joes.

Poisoning the Well

Also called a smear tactic, it's the act of presenting negative information that is irrelevant before presenting an argument, which makes that argument, or person, seem untrustworthy. Before you listen to what he has to say, may I remind you that he has been in jail.

Primary source: John Henry Newman

Appeal to Consequences

An argument that attempts to prove a hypothesis true or false because the consequences of it being true or false are desirable or undesirable. It's a logical fallacy.

Behavioral Inevitability

The notion that human behavior, and its inherent biases, will always remain. As Voltaire said: History never repeats itself; man always does.

Self-Handicapping

The tendency to resist putting in an effort to do something because of a worry that failing might put a dent in one's self-esteem.

Primary source: Edward E. Jones; Steven Berglas

False Uniqueness Effect

An attributional cognitive error of assuming that one's qualities, traits, and personal attributes are unique when in reality they are not. In essence, it's the opposite of imposter syndrome.

Backfiring Effect

The tendency to enforce one's existing beliefs about something when presented with disconfirming evidence. A study that looked at political voting showed that introducing people to negative information about their favored political candidate would often cause them to increase their support for that candidate.

Positive Illusions

A form of self-deception that causes individuals to think inflatedly about themselves, their decisions, and abilities to avoid short-term discomfort or raise self-esteem. A positive illusion might cause a negative spiral of justifications about worse and worse decisions.

Primary source: Shelley Taylor; Jonathon Brown

Ironi Process Theory

The psychological process of attempting to suppress certain thoughts, making those thoughts more likely to resurface in one's mind.

Primary source: Daniel Wegner

Aumann's Agreement Theorem

Named after Israeli-American mathematician Robert Aumann, it's the notion that two rational people in an opposing argument can't and shouldn't come to the conclusion of agreeing to disagree if they have common knowledge of each other's beliefs.

Primary source: Robert Aumann

Ostrich Effect

As ostriches bury their heads in the sand to avoid danger, the ostrich effect is the tendency to avoid opposing information to what one desperately wants to be right.

Primary source: Dan Galai; Orly Sade

Bounded Rationality

Limits to the capacity of the human mind make it impossible to contain and recall all information obtained, and therefore, rationality is also limited.

Primary source: Herbert Simon

Fluency Heuristic

Related to the narrative fallacy, fluency heuristic is the tendency to believe more in ideas that are easy to explain rather than those that are hard to comprehend.

Persian Messenger Syndrome

The act of blaming the bearer of negative news.

As Charlie Munger has said: The Persians really did kill the messenger who brought the bad news. You think that is dead? I mean you should've seen Bill Paley in his last 20 years. He didn't hear one damn thing he didn't want to hear. People knew that it was bad for the messenger to bring Bill Paley things he didn't want to hear. Well that means that the leader gets in a cocoon of unreality, and this is a great big enterprise, and boy, did he make some dumb decisions in the last 20 years.

Okrent's Law

A law stated by writer Daniel Okrent referring to the phenomenon of the press providing legitimacy to unsupported fringe viewpoints in an effort to appear even-handed.

He once said: The pursuit of balance can create imbalance because sometimes something is true.

Primary source: Daniel Okrent

Vierordt's Law

In 1868, German physiologist Karl von Vierordt created this law stating that humans perceive time at different magnitudes over different durations. We underestimate long periods of time and overestimate short periods of time.

Primary source: Karl von Vierordt

Cunningham's Law

Ward Cunningham, the creator of the first wiki, said: The best way to get the right answer on the Internet is not to ask a question. It's to post the wrong answer.

If you constantly express anger in your private conversations, your friends will likely find you tiresome, but when there's an audience, the payoffs are different; outrage can boost status.

The internet promotes the same dynamic as road rage: once you're arguing with a computer (or vehicle) rather than a person, social norms tend to vanish.

Primary source: Ward Cunningham

Tyranny of Small Decisions

A situation where a series of small, individually rational decisions creates a path dependence that might negatively alter the context of decisions made subsequently to the point where the original desire is irreversibly destroyed.

Primary source: Alfred Kahn

Hyperbolic Discounting

The tendency to show a higher preference for the reward that comes sooner rather than later. Humans discount future events. This is why we have interest rates.

Primary source: Richard Herrnstein

Delayed Gratification

The process an individual undergoes when resisting the temptation of an immediate reward in preference for a later reward.

Observer Effect

A situation where an individual is being observed, but the very observation alters that individual's actions. Merely observing a phenomenon inevitably changes the same phenomenon.

Golem Effect

Related to the observer effect, performance tends to decline when supervisors, teachers, or bosses have low expectations of one's abilities.

Maslow's Hierarchy of Needs

A motivational theory created by psychologist Abraham Maslow in a 1943 paper stating that humans have five categories of needs in order: physiological, safety, love, esteem, and self-actualization. Higher needs in the hierarchy emerge when the previous need is appropriately satisfied.

Primary source: Abraham Maslow

Bystander Effect

A social observation that people are less likely to help a victim when others are present as an audience. The greater the number of bystanders, the less likely is it that one of them will help.

Primary source: John M. Darley; Bibb Latané

Hot Hand Fallacy

Describes the positive expectation that an event will occur that has already been preceded by a consequence of the same event. Sports fans have a tendency to assume that a particular player having a streak of successful shots has an increased probability of making the next shot, irrespective of the player's historical shooting record.

Primary source: Amos Tversky; Thomas Gilovich; Robert Vallone

Gambler's Fallacy

Also known as the Monte Carlo fallacy, it's the mistaken belief that a run of specific results in a random process makes it less or more likely to occur the next time.

For example, a series of 10 coin flips might all land on heads. Under the gambler's fallacy, a person might expect that the next coin flip is more likely to land on tails the next time.

Primary source: Daniel Kahneman; Amos Tversky

Acton's Law

Power tends to corrupt, and absolute power corrupts absolutely.

Primary source: John Dalberg-Acton

Brandolini's Law

The amount of energy needed to refute bullshit is an order of magnitude larger than to produce it.

Primary source: Alberto Brandolini, an Italian programmer

Peltzman's Law

People are more likely to engage in risky behavior when security measures have been mandated.

Primary source: Sam Peltzman

Mental Models in Numeracy and Interpretation

Power Laws

When a relative change in one quantity results in a proportional relative change in the other quantity. Few empirical distributions fit a power law for all their values but rather follow a power law in the tail. For example, the distribution of income in a market economy is following a power law because inequality is built into the process of wealth accumulation itself. Big cities draw more people. Capital in corporations attracts more capital. Profits generate greater profit. The Pareto principle is a type of power law.

Permutations and Combinations

With permutations, we care about the order of the elements, whereas with combinations we don't. The mathematics of permutations and combinations leads us to understand the practical probabilities of the world around us and is enormously important.

Primary source: Blaise Pascal; Pierre de Fermat

Algebra

The study and manipulation of mathematical symbols or letters to demonstrate equivalence or inequivalence of subjects. Algebra is considered an essential part of any study within mathematics, science, or engineering, as well as such applications as medicine and economics.

Multiplying by Zero

Any number multiplied by zero, no matter how large, becomes zero. And yet, this is often learned the hard way. When trying to compound returns it's fatal to multiply your capital by zero.

Randomness

Randomness is present everywhere in the real world but it often doesn't fit how we think about the world. An erroneous strive for pattern-seeking sometimes makes us see patterns that are not there. As Nassim Taleb puts it, we are "fooled by randomness".

Stochastic Processes

A family of random variables on the same probability space. Brownian motion and the random walk theory are stochastic processes.

Gambler's Ruin

Playing a negative-probability game persistently enough guarantees to go broke.

Gambler's ruin might also explain the case where a gambler goes broke even if he might have a positive expected value on each bet. This happens if the gambler raises the bet to a fixed fraction of the bankroll when winning, but doesn't reduce it when losing.

Primary source: Blaise Pascal; Pierre de Fermat

Read: [The Kelly Criterion Applied to Long-Term Value Investing](#)

Compounding

A powerful force that happens when interest is regularly added to the sum which earned interest on the previous sum. Said to be called the "8th wonder of the world" by Albert Einstein, it's a mathematical concept that lays the foundation for the field of finance but is clearly not bounded by the realm of finance itself. Knowledge, capability, ideas, relationships, and so on all build on the basis of compound interest. Naval Ravikant has said: Play iterated games. All the returns in life, whether in wealth, relationships, or knowledge, come from compound interest.

Understanding the time value of money is crucial because compounding plays out over the long term. In the short term, incremental gains are often hardly noticed.

Churn

Churn is a form of entropy. Basically, it's the measure of the number of people or items moving out of a collective group over a specified period of time (think customers of insurance companies or subscription services). Reducing churn requires constant care of the group.

Churn and growth rates are diametrically opposed factors as one measures the loss of a group and the other measures acquisition into the group.

Law of Large Numbers

The law stating that the average of the results obtained from a large number of events should be close to the expected value of those events and will tend to become closer to the expected value as even more events occur. It was proved in 1713 by Swiss mathematician Jakob Bernoulli.

In business, the law of large numbers is evident in relation to percentage-wise growth rates. As a business grows larger, the percentage rate of growth becomes increasingly difficult to maintain.

Read: [The Kelly Criterion Applied to Long-Term Value Investing](#)

Probability Distributions

Statistical functions that describe all the possible values and likelihoods that a random variable can take within a given range. How the distribution of these values is laid out is dependent on its standard deviation, skewness, and kurtosis. The most common of these is the normal distribution—or bell curve—which is found frequently in finance, investing, science, and engineering.

Central Limit Theorem

If you add a large number of independent random variables, possibly with different probability distributions, but with finite variances, the sum will go towards a normal distribution.

Primary source: Pierre-Simon Laplace

Confidence Interval

The measure that explains to what degree a sample estimate might explain the true value of a parameter when tested on a population. It's the range of values we are fairly sure our true value lies in. Not understanding the confidence interval is often what creates financial trouble.

Regression to the Mean

The occurrence that happens when a number of observations follow the law of large numbers. If a random variable is extreme on its first measurement, regression to the mean suggests that it will be closer to the mean or average on its subsequent measurements. It's easy to understand the concept. But not understanding its limitations or where it's applicable can prove very dangerous. For example, large amounts of money have been subject to opportunity cost in the stock market by erroneously buying below-average price-to-book companies believing their values will follow the regression to the mean principle. That is until the investor realizes that the price is just the numerator and the book value—the denominator—starts to turn on the thesis.

Order of Magnitude

A quantitative measure generally used to make very approximate comparisons. If two numbers differ by one order of magnitude, one is about ten times larger than the other.

Kelly Criterion

In 1956, a young scientist at Bell Labs named John Larry Kelly Jr. came up with a simple formula for optimal bet sizing based on the better's edge and odds of winning. It was essentially built on Claude Shannon's information theory and Bernoulli's St. Petersburg Paradox.

The formula is:

Edge / odds = Fraction of your bankroll to bet each time

As an example, taking a positive risk/reward bet of 1:2 with a 50% chance of either outcome, the Kelly criterion suggests that the optimal bet size of the bankroll is 25% (reward, if positive odds play out, is 2 and edge is 0.5, so $0.5 / 2 = 25\%$). No other approach can increase wealth faster than the Kelly criterion without increasing the odds of wiping out the bankroll.

Primary source: John Larry Kelly, Jr.

J-Curve

An effect where a curve initially falls, then steeply rises above the starting point.

The model is usually applied in terms of analyzing the path of a country's terms of trade following a devaluation or depreciation of its currency, under a set of conditions.

In private equity, the J-curve is used to illustrate the historical tendency of private equity funds to deliver negative returns in early years and investment gains in the outlying years as the portfolios of companies mature.

Base Rate Neglect

A tendency to ignore the a priori probability of something by putting heavier weight on appealing information about an individual's case. Only 6% of applicants make it into this school, but my son is brilliant. I'm sure they're going to accept him!

Primary source: Daniel Kahneman; Amos Tversky

Anscombe's Quartet

Developed by statistician Francis Anscombe, Anscombe's quartet is when presumably identical sets of numbers do not at all look identical when graphed. Numerical calculations are exact, but graphs are rough.

Primary source: Francis Anscombe

Selection Bias

An experimental error that happens when sample data is not representative of the population as a whole.

Berkson's Paradox

A case where conditional probability and correlations are counterintuitive due to a sampling or selection bias.

Suppose a stamp collector has 1000 postage stamps, of which 300 are pretty and 100 are rare, with 30 being both pretty and rare. 10% of all the collector's stamps are rare and 10% of the pretty stamps are rare, so prettiness tells nothing about the rarity of the stamps.

Primary source: Joseph Berkson

Apophenia

A psychological phenomenon where random and meaningless impressions are perceived as meaningful. It's a way to comfort the mind in explaining how the world works. To see patterns and connections when none are present is also called patternicity.

Primary source: Klaus Conrad

Neglect of Probability

The tendency to disregard probability in decision making under uncertainty. Small risks are either neglected entirely or hugely overrated. Hindsight bias is a common result of the tendency to neglect probability.

Ergodicity

Born from the field of thermodynamics, ergodicity is a case where population probabilities don't apply to individual events but are evened out as time passes. One might not die from a single game of Russian roulette but will most certainly die if playing the game enough times.

Primary source: Ludwig Boltzmann

Moral Luck

The act of praising a person for a good deed they didn't have full control over. As Nassim Taleb puts it: Avoid calling heroes those who had no other choice.

Primary source: Bernard Williams

Friendship Paradox

Most people have fewer friends than their friends have, on average. The reason is a type of sampling bias in which people with more friends are more likely to be one of your friends. In reality, the friendship paradox is a contradiction because most people believe that they have more friends than their friends have.

Primary source: Scott L. Feld

Clustering Illusions

Falsely assuming that streaks or clusters of small samples in a large pool of data in random distributions indicate a non-random distribution.

Primary source: Thomas Gilovich

Nonlinearity

Closely related to the Kantian fairness tendency, nonlinearity is a situation where there is not a straight-line or direct relationship between an independent variable and a dependent variable. The output is not proportional to the change of the input, posing to sometimes appear chaotic, unpredictable, or counterintuitive. A very important topic to understand.

Moderation

A situation where the relationship between two variables depends on a third variable. If two objects are stuck together in thick and thin, that might be due to a third variable – glue.

Denomination Effect

Even though a \$50 bill has the same value as 10 \$5 bills, we tend to feel that the 10 bills are worth less. The denomination effect is also evident in the case of stock splits.

Primary source: Priya Raghubir; Joydeep Srivastava

Woozle Effect

When frequent citation of previous information that lacks evidence misleads individuals into believing it's evidence. As Daniel Kahneman puts it: A reliable way to make people believe in falsehoods is frequent repetition, because familiarity is not easily distinguished from truth.

The Scientific Method

An empirical method of acquiring knowledge through systematic observation, measurement, and experiment, and the formulation, testing, and modification of hypotheses.

Proxy

A variable that serves instead of an immeasurable other variable. The proxy must be close to the replaced value in order for it to be a good proxy.

Inflection Point

A point on a curve at which the curve changes from being concave (concave downward) to convex (concave upward), or vice versa.

Simpson's Paradox

A case where a certain trend seems evident in different groups of data but is not evident when these groups are combined.

Primary source: Edward H. Simpson

Surface Area

The amount of space that is outside of a solid object. If building a tank larger than it is, the amount of steel used to grow the tank will be able to hold more. It's a non-linear relationship.

Maxima and Minima

Known collectively as the extrema, maxima and minima are the highest and lowest points of value in a function. Pierre de Fermat was one of the first mathematicians to propose a general technique, adequality, for finding the maxima and minima of functions.

Sensitivity Analysis

A method of assessing the stability of research results by changing conditions in each variable.

Benford's Law

Describes how different figures are distributed as first figures in statistics. For example, Benford's law states that the number 1 should be the first digit in 30.1% of the cases, the number 2 in 17.6% of the cases and the figure 9 in 4.6% of the cases in a very large amount of data.

Primary source: Frank Benford

Black Swan Events

Rare events that have a large impact are difficult to predict and are beyond normal estimates.

Primary source: Nassim Taleb

Goodhart's Law

When a measure becomes a target, it ceases to be a good measure. When we set one specific goal, people will tend to optimize for that objective regardless of the consequences.

Primary source: Charles Goodhart, economist

Mental Models in Thinking**Decision Trees**

A tree-like visualization of how action leads to another series of possible consequences and outcomes. Algorithms are largely based on decision trees.

Probabilistic Thinking

Probabilities are the rules of the world, and thus probabilistic thinking is one of the most critical traits and skills to adopt. But John Maynard Keynes also said: It's better to be roughly right than precisely wrong.

Second-Order Thinking

Thinking in terms of effects and the effects of those effects. Second-order thinkers ask themselves the question; "and then what"?

Second-order thinking is largely related to thinking in terms of permutations and combinations in combination with decision trees. This is crucial in the investment business. As Ray Dalio says: Failing to consider second and third-order consequences is the cause of a lot of painfully bad decisions, and it is especially deadly when the first inferior option confirms your own biases.

Bayesian Updating

The method of updating a probability estimate for a hypothesis as new evidence or information becomes available. It's hugely in line with how the world works because Bayesian updating is closely related to subjective probability. It was named after Reverend Thomas Bayes.

Primary source: Thomas Bayes

Bloom's Taxonomy

Created by Benjamin Bloom in 1956, Bloom's taxonomy is a set of three hierarchical orders of thinking of any subject in terms of levels. It consists of three learning domains: the cognitive, affective, and psychomotor, and it then assigns to each of these domains a hierarchy that corresponds to different levels of learning where each level subsumes the levels that come before it.

The levels of the cognitive domains are ordered as knowledge, comprehension, application, analysis, synthesis, and evaluation.

Primary source: Benjamin Bloom

Circle of Competence

Moving out of one's circle of competence is prone to blind spots that one is unaware of. Yet often, when one is not able to define or think about one's circle of competence, it leads to the same degree of confidence as to when one is really operating within the circle of competence. This is dangerous.

The concept is important because it allows bright people to utilize limited, really valuable insights in a very competitive world when they're fighting against other very bright, hardworking people.

Primary source: Warren Buffett

First Principles

The basic assumptions that can't be deduced any further in a specific field. Aristotle defined first principles as; the first basis from which a thing is known. It's the idea of breaking down complicated problems into its basic and only essential elements.

Primary source: Aristotle

Thought Experiment

An imaginary experiment used to solve difficult problems and their potential consequences. The concept was very effectively used by Einstein to discover the theory of relativity by imagining traveling on a beam of light.

Inversion

A thinking tool to get to the root of a problem by thinking of it in reverse. Carl Gustav Jacob Jacobi told his students that when looking for a research topic they should; invert, always invert.

Primary source: Carl Gustav Jacob Jacobi

The 5 Whys

Asking yourself 5 whys about a given subject is a great way to push yourself to find the truth and achieve rationality.

Primary source: Sakichi Toyoda

Occam's Razor

All else equal, Occam's razor is the idea of preferring the theory with the fewest assumptions. Also called the parsimony principle, it's a basic idea to all science and suggests to choose the simplest scientific explanation that fits the evidence. In terms of tree-building, this means that, *ceteris paribus*, the best hypothesis is the one that requires the fewest evolutionary changes.

Primary source: William of Ockham

Hanlon's Razor

Inspired by Occam's razor, it's a way of eliminating unlikely explanations for human behavior. Robert J. Hanlon said: Never attribute to malice that which can be adequately explained by stupidity.

Primary source: Robert J. Hanlon

Maslow's Hammer

If all you have is a hammer, everything looks like a nail. Also known as the law of the instrument. It's a law because an instrument can pretty much only be used in one way to fulfill its purpose of creation.

Primary source: Abraham Maslow

Divergent vs. Convergent Thinking

Divergent thinking is the process of thinking by exploring multiple possible solutions in order to generate creative ideas. Convergent thinking is the process of figuring out a concrete solution to any problem. The key is to strike a balance.

Primary source: Joy Paul Guilford

Chronological Snobbery

The argument or thinking that the stuff of earlier times is inferior to that of the present, simply due to societal progress.

As C.S. Lewis puts it: The assumption that whatever has gone out of date is on that account discredited. You must find why it went out of date. Was it ever refuted (and if so by whom, where, and how conclusively) or did it merely die away as fashions do? If the latter, this tells us nothing about its truth or falsehood. From seeing this, one passes to the realization that our own age is also 'a period,' and certainly has, like all periods, its own characteristic illusions.

Lewis made it a rule of thumb that one should read at least as many old books as new ones.

Primary source: C. S. Lewis; Owen Barfield

Weasel Words

The illusion that when someone wants to make it seem like they've given a clear answer to a question or made a direct statement when actually they've said something inconclusive or vague. Words like "better", "improved", "gains" do not say how much in terms of a complete argument.

Knightian Uncertainty

Economist Frank Knight argued that risk applies to situations where we don't know the outcome of a situation but can measure its probabilities. On the other hand, uncertainty applies to situations where we can't know all the information needed in order to set accurate probabilities in the first place.

Primary source: Frank Knight

Map-Territory Relation

The relationship between an object and a representation of that object is always abstract – like a map vs. the territory it represents. A person who has seen and heard descriptions of an apple, but has never tasted it, will not know how it tastes.

Primary source: Alfred Korzybski

All Models Are Wrong

Closely related to the map-territory relation, it's an aphorism in statistics commonly stating: All models are wrong, but some are useful. Attributed to statistician George Box, the thinking is considered applicable to all scientific models.

Primary source: George Box

Middle Ground Fallacy

The fallacy of compromising two opposing views to land on the middle ground just because it's the middle ground. For example, if one person says that all elephants can fly, another says that no elephants can fly, it's a fallacy to agree that perhaps some elephants can fly.

Eisenhower Matrix

Dwight Eisenhower, the 34th President of the United States, had to make tough decisions continuously about which of the many tasks he should focus on each day. And so he created the Eisenhower matrix to decide on and prioritize tasks by urgency and importance, sorting out less urgent and important tasks which he should either delegate or not do at all. He said: What is important is seldom urgent, and what is urgent is seldom important.

Primary source: Dwight Eisenhower

Systemics

The study of systems, how they work, how they are related to larger systems, and how they break down or are prone to bottlenecks. It's a disciplined approach for examining problems more completely.

Primary source: Mario Bunge

Lateral Thinking

First coined by Edward de Bono in 1967, it's a method of thinking across otherwise irreconcilable dialectical disciplines and then arriving at solutions that cannot be arrived at via deductive or logical means. We might call this "thinking outside the box".

Consider this: A man walks into a bar and asks the barman for a glass of water. The barman pulls out a gun and points it at the man. The man says "thank you" and walks out. Why?

The man had hiccups.

Primary source: Edward de Bono

Historical Wisdom

Studying the past intensely to understand the present and the future because the past makes up the vast majority of events. Scottish historian Niall Ferguson has said: The dead outnumber the living 14 to 1, and we ignore the accumulated experience of such a huge majority of mankind at our peril.

Paradigm Shift

When an important change occurs that replaces the usual way of thinking about or doing something.

Primary source: Thomas Kuhn

Abduction

A term related to both induction and deduction, where the researcher moves between theory and empiricism to gradually allow understanding to emerge.

Primary source: Thomas Kuhn

Chauffeur Knowledge

Charlie Munger explains in the story of Max Planck and his chauffeur: I frequently tell the apocryphal story about how Max Planck, after he won the Nobel Prize, went around Germany giving the same standard lecture on the new quantum mechanics.

Over time, his chauffeur memorized the lecture and said, "Would you mind, Professor Planck, because it's so boring to stay in our routine. [What if] I gave the lecture in Munich and you just sat in front wearing my chauffeur's hat?" Planck said, "Why not?" And the chauffeur got up and gave this long lecture on quantum mechanics. After which a physics professor stood up and asked a perfectly ghastly question. The speaker said, "Well I'm surprised that in an advanced city like Munich I get such an elementary question. I'm going to ask my chauffeur to reply.

Planck knowledge has paid the dues and gained the aptitude. Chauffeur knowledge just learned the talk.

Primary source: Charlie Munger

Pascal's Wager

Blaise Pascal's famous argument for believing in God. Pascal argued that it's always a better "bet" to believe in God because the expected value of the gain to be achieved by believing in God is always greater than the expected value in the case of unbelief.

On the question of God's existence, a third option is excluded (*tertium non datur*). There are only two options:

1. God exists
2. God does not exist

Thus, one will be forced to bet on one of the options:

1. If one bets that God exists, one would win everything if one is right and would lose nothing.
2. If one bets that God doesn't exist, nothing can be won, but one can lose everything.

Primary source: Blaise Pascal

Alder's Law

If something cannot be settled by experiment then it is not worthy of debate.

Mental Models in Systems.

Scale

As a system or an organization performs more and more of the same type of work, it will tend to acquire efficiencies over time, but it might also acquire inefficiencies – like bureaucracy. When scale turns into an advantage, it's due to positive feedback loops.

It's safe to conclude that scale advantages can create extremely durable economic moats, but it's also important to recognize that economies of scale don't necessarily create moats.

As other car producers closed the gap with Ford's level of productivity, Ford's scale advantage disappeared.

Pareto Principle

Also known as the 80/20 rule and as a form of power law, the Pareto principle states that, for many situations, roughly 80% of the situation's effects come from 20% of the causes. It was developed by Vilfredo Pareto who showed that approximately 80% of the land in Italy was owned by 20% of the population.

The principle can be applied in a wide range of areas such as manufacturing, management, human resources, and personal time management. However, though broadly applied, it does not apply to any scenario. Be careful with it.

Primary source: Vilfredo Pareto

Law of Diminishing Returns

In all productive processes, adding more of one factor of production will, *ceteris paribus*, at a certain point result in lower incremental per-unit returns. The law is existing because there are always constraints in the world. Too many cooks spoil the broth.

Algorithms

A way to solve a problem by way of termination. An algorithm consists of sets of rules to complete the task in a series of steps. An obvious example is a recipe.

Primary source: Muḥammad ibn Mūsā al-Khwārizmī

Margin of Safety

Warren Buffett has said on the margin of safety: You have to have the knowledge to enable you to make a very general estimate about the value of the underlying business. But you do not cut it close. That is what Ben Graham meant by having a margin of safety. You don't try to buy businesses worth \$83 million for \$80 million. You leave yourself an enormous margin. When you build a bridge, you insist it can carry 30,000 pounds, but you only drive 10,000-pound trucks across it. And that same principle works in investing. While useful in investing, the margin of safety is a methodological issue that is an incredibly useful concept in nearly any life endeavor.

Primary source: Benjamin Graham

Network Effects

If only one person is participating in a social network, that social network will have no value. Since network effects work in terms of returns to scale, the network's value is driven by the number of users coming into the network. Sometimes, that turns into a winner-take-all scenario.

Primary source: Theodore Vail

The Tipping Point

Popularized by Malcolm Gladwell, the tipping point is the point at which a product or trend goes viral – or turns into an epidemic. Gladwell introduces three variables that create the tipping point: the law of the few, the stickiness factor, and the power of context. A powerful mental model for how things gain traction in society.

Primary source: Malcolm Gladwell

Entropy

A measure of the number of possible arrangements the atoms in a system can have. In other words, it's a measure of uncertainty or randomness. Essentially, entropy is evident because of probability since there are only a limited set of ordered states in a system but an infinite amount of chaotic states.

Primary source: Rudolf Clausius

The Second Law of Thermodynamics

Directly related to entropy, the second law of thermodynamics states that the total entropy of an isolated system will inevitably increase over time and will only remain still if all processes in the system are reversible.

Imagine a bunch of balls bouncing around in a box in an initially ordered way as a pattern. Over time, the balls will inevitably bounce around more chaotically and the entropy of the system thus increases.

Primary source: Rudolf Clausius

Principle of Minimum Energy

As a restatement of the second law of thermodynamics, the principle of minimum energy states that for a closed system with fixed entropy, the total energy is minimized at equilibrium.

Feedback Loops

When the outcome of a system amplifies and reinforces the system itself in either positive or negative fashion. The output is rooted back as an input for the next stage. A great way to think about really difficult problems is to try and depict cause-and-effect relationships by connecting them in loops.

It's largely related to systems thinking. Systems thinking is not linear and it doesn't happen in a straight line — it happens in cycles, loops, contours.

Reflexivity

With George Soros as its primary proponent, reflexivity is a theory that feedback loops between expectations and economic fundamentals can cause price developments that substantially and persistently deviate from equilibrium prices. Soros's theory of reflexivity runs counter to the ideas of economic equilibrium, rational expectations, and the efficient market hypothesis.

Primary source: George Soros

Complex Adaptive Systems

An extremely important mental model in which a perfect understanding of the individual parts in a system does not automatically convey a perfect understanding of the system's behavior as a whole. Examples of complex adaptive systems include cities, large corporations, markets, governments, and so on.

Michael Mauboussin explains: If you examine the colony on the colony level, forgetting about the individual ants, it appears to have the characteristics of an organism. It's robust. It's adaptive. It has a life cycle. But the individual ant is working with local information and local interaction. It has no sense of the global system. And you can't understand the system by looking at the behavior of individual ants. That's the essence of a complex adaptive system—and the thing that's so vexing. Emergence disguises cause and effect. We don't really know what's going on.

Pari-Mutuel Systems

Betting systems in which all bets are placed in a collective pool and payoff odds are calculated by sharing the pool among all winning bets after house take. A common example is horse race betting.

Charlie Munger has said: The model I like—to sort of simplify the notion of what goes on in a market for common stocks—is the pari-mutuel system at the racetrack. If you stop to think about it, a pari-mutuel system is a market. Everybody goes there and bets and the odds change based on what's bet. That's what happens in the stock market.

Butterfly Effect

A phenomenon where a small change in an initial condition can have a huge effect in a future condition. The term comes from an analogy where a butterfly flaps its wings in Chicago and a tornado occurs in Tokyo.

The social impact of the butterfly effect theory is undeniable in today's inter-connected world. Butterfly effects make social systems fundamentally unpredictable.

Preferential Attachment

When what is popular or perceived as better grows even more than what is less popular. Network effects feed on preferential attachment.

Emergence

When the sum of something cannot be explained by simple additions of its components, e.g. when the sum is greater than the parts.

Irreducibility

When a system or object is incapable of being reduced, diminished, or simplified further.

Tragedy of the Commons

When a depletable resource is shared in a system where the individual users act in their own self-interest, it will tend to be depleted.

If fishing provides an income and no one is there to regulate the fishing pond, then each fishers would act according to their own interest and try to catch as many fish as possible even if all the other fishers are doing the same thing.

Primary source: William Forster Lloyd

Gresham's Law

A system named after financier Sir Thomas Gresham where "bad money drives out good". The law was originally based on how minted coins tended to decrease in terms of the amount of precious metals used in them.

Consider two coins with the same legal tender face value. One of them is made of silver and the other of copper. According to Gresham's law, individuals will hold onto the silver coins and use just the copper ones for payment.

The law is not only applicable to currencies. Avoid participating in systems where good behavior cannot win.

Primary source: Sir Thomas Gresham

Antifragility

Nassim Taleb, the originator of the term, said the following on antifragility: Some things benefit from shocks; they thrive and grow when exposed to volatility, randomness, disorder, and stressors and love adventure, risk, and uncertainty. Yet, in spite of the ubiquity of the phenomenon, there is no word for the exact opposite of fragile. Let us call it antifragile. Antifragility is beyond resilience or robustness. The resilient resists shocks and stays the same; the antifragile gets better.

Primary source: Nassim Taleb

Redundancy

The concept of backup systems in engineering. It involves duplication of critical components or functions of a system with the intention of increasing its reliability, or robustness. A suspension bridge's numerous cables are a form of redundancy.

Via Negativa

The action of improving a system by removing elements from it. The paradox of choice states that more options can lead to poorer decisions. Via negativa is the solution.

Warren Buffett's 5/25 rule is a method of via negativa: List 25 goals you want to achieve in the next ten years. Select the top five and ignore the remaining 20 at all costs.

Lindy Effect

The idea that non-perishable objects, ideas, or technologies are expected to live proportionally to their current age. If something has lived for X years, it can be expected to live for another X years. Because every additional period of survival implies a longer remaining life expectancy, expected mortality decreases with time.

Primary source: Albert Goldman

Bullwhip Effect

A chain reaction where an initial reaction to an expected outcome turns to bigger reactions later in the chain because of a lack of complete information about expectations earlier in that chain.

Primary source: Jay Forrester

Parkinson's Law

Work expands to fill the time available for its completion. It was first coined by Cyril Northcote Parkinson in a humorous essay for the Economist in 1955.

Primary source: Cyril Northcote Parkinson

Symmetry of Ignorance

When a problem is so difficult or impossible to solve that every participant attempting to solve it is basically shooting in the dark.

It's a notion suggested by Horst Rittel in a 1972 article in which he wrote: The expertise and ignorance is distributed over all participants in a wicked problem. There is a symmetry of ignorance among those who participate because nobody knows better by virtue of his degrees or his status. There are no experts (which is irritating for experts), and if experts there are, they are only experts in guiding the process of dealing with a wicked problem, but not for the subject matter of the problem.

Base Rates

The a priori probability of an activity about to be done, e.g. the success rate of everyone who's done what you're about to try.

System Justification Theory

People tolerate unjust and inefficient systems if their personal incentives are aligned to defend or maintain it. The theory was initially proposed by John T. Jost and Mahzarin R. Banaji in 1994.

Primary source: John T. Jost; Mahzarin R. Banaji

Sturgeon's Law

An adage cited as ninety percent of everything is crap. Quoted by science fiction author Theodore Sturgeon, it represents the belief that in general, the vast majority of the work that is produced in any given field is of low quality.

Primary source: Theodore Sturgeon

Ringelmann Effect

As a group increases its amount of members, individuals of that group tend to become increasingly less productive. It was named after French agricultural engineer Maximilien Ringelmann.

Consider a tug of war. As more people are involved in it, their average performance tends to decrease because each participant feels that their own effort is not critical.

Primary source: Maximilien Ringelmann

Planck's Principle

Max Planck said: A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die and a new generation grows up that is familiar with it.

Primary source: Max Planck

Group Attribution Error

Falsely assuming that the views and decision outcomes of a collective group reflect the view of each member in that group.

Primary source: Scott T. Allison; David M. Messick

90-9-1 Rule

In a social media network, only 1 percent of users will actively create content; another 9 percent will participate by commenting, rating, or sharing the content; and the last 90 percent will watch, look and read without responding.

Braess's Paradox

An observation by German mathematician Dietrich Braess who noticed that adding a road to a particular congested road traffic network would make traffic worse due to an increase in shortcuts becoming popular and overcrowded.

Primary source: Dietrich Braess

Perfect Solution Fallacy

Also called the Nirvana fallacy, it's a false dichotomy suggesting that a perfect solution exists to a problem and that courses of action should be rejected if just a small part of the problem remains.

Primary source: Voltaire

Peter Principle

Employees rise in an organization through promotion until they end in a position in which they are incompetent. A principle developed by Laurence J. Peter.

Primary source: Laurence J. Peter

Foundational Species

Species that have a pillar role in supporting an ecosystem or community. Without the presence of these foundational species, many other species in the ecosystem couldn't sustain their existence. Coral is a foundational species in nature and the Federal Reserve is one in the world economy.

Primary source: Paul K. Dayton

Google Scholar Effect

Google Scholar's algorithm is an enhancer of preferential attachment since highly cited papers appear in top positions and gain more citations. Meanwhile, new papers hardly appear in top positions and therefore get less attention, regardless of their contribution to their fields.

Primary source: Paul K. Dayton

Rebound Effect

If a 5% improvement in car fuel efficiency results in only a 2% drop in fuel use, it means there is a 60% rebound effect. The 3% discrepancy might be explained by driving faster or further than before.

Murphy's Law

All that can happen, will happen.

Primary source: Edward Murphy

Campbell's Law

Social scientist Donald T. Campbell has said: The more any quantitative social indicator is used for social decision-making, the more subject it will be to corruption pressures and the more apt it will be to distort and corrupt the social processes it is intended to monitor. Quantitatively measuring the wrong stuff and, as a result, accidentally setting the wrong incentives is a very dangerous position to put oneself in because it's rarely noticed before the system collapses. Take Enron's accounting procedures. It's an example of the cobra effect.

Primary source: Donald T. Campbell

Path Dependence

In accordance with decision trees, history matters in terms of what options there are to decide on for the future. The set of decisions people face for any given circumstance is limited by the decisions they have made in the past. As explained through the tyranny of small decisions, path dependence might end up as an irreversible negative surprise if not properly applying second-order thinking.

Externality

When a third party is subject to the cost or benefit that it did not have any control over. Industry pollution is a negative externality that may affect the health of nearby residents. A positive externality might be an individual who maintains an attractive house that benefits the neighbors in the form of increased market values of their properties.

Primary source: Henry Sidgwick

Open vs. Closed Platform

An open platform, or system, is one in which its contents or functionalities are able to be altered in other ways than the original creator of the platform intended. On the other hand, a closed platform is one which is "off the rack" – the creator keeps control over its contents.

Moore's Law

The observation that the number of transistors on a microchip doubles roughly every two years while the cost of computers is halved. Experts agree that computers should reach the physical limits of Moore's Law at some point in the 2020s because the high temperature of transistors would make it impossible to make smaller circuits.

Gordon E. Moore said himself about the limits to the law: It can't continue forever. It is the nature of exponential functions. They eventually hit a wall.

Primary source: Gordon Moore

Metcalfe's Law

The value of a communication system grows proportionally to the square of the number of users of the system (N^2) – or, more precisely, with the rate: $N(N-1)$.

Metcalfe's law was originally formulated by Robert Metcalfe about Ethernet, but the law explains a number of network effects of technologies such as the Internet, the World Wide Web, and Microsoft Windows.

Primary source: Robert Metcalfe

Theory of Constraints

A philosophy of governance introduced by Dr. Eliyahu M. Goldratt which helps and leverages organizations to achieve their goals. The title comes from the assertion that any manageable system is limited to achieving several of its goals by a very small number of constraints and that there is always at least one constraint.

Primary source: Eliyahu M. Goldratt

Amara's Law

Technology is overestimated in the short run and underestimated in the long run.

Primary source: Roy Amara

Mental Models in the Biological World

Incentives

Contingent encouragers that motivate humans and animals to do certain actions. It's based on the idea that people do what is in their own best interest. It might be extraordinarily difficult to discourage a behavior if that behavior is incentivized, and it might be equally difficult to encourage a behavior if it's disincentivized.

Ecosystems

An ecosystem is used to describe a complete environment in nature with all living organisms and non-living elements.

The first basic principle of ecology is that every living organism has an ongoing and lasting relationship with every other element that is part of its environment. Therefore, it is crucial to see all ecological conditions as part of systems development.

Primary source: Arthur Tansley

Niches

In ecosystems, a participant of the system might flourish more in a niche to which it is adapted than it would any other way. Closely related to the circle of competence.

Evolution by Natural Selection

The process by which organisms change over time as a result of changes in heritable physical or behavioral traits – or what is called phenotype. Developed by Charles Darwin in 1859, the theory is one of the best-substantiated in the history of science, supported by evidence from a wide variety of scientific disciplines.

When Darwin worked on the theory, he was a relentless destroyer of his own ideas. He once said: To kill an error is as good a service as, and sometimes even better than, the establishing of a new truth or fact.

Primary source: Charles Darwin; Alfred Russel Wallace

Cooperation

When organisms, animals, or humans find a common good to work for, which is greater than the cooperators' individual selfish benefits, they tend to cooperate towards that common good.

Prisoner's Dilemma

Individual self-interest may not favor cooperation.

The prisoner's dilemma is a problem in which two individuals acting in their own self-interests do not create an optimal outcome. The typical dilemma is set up in such a way that both individuals choose to protect themselves at the expense of the other individual.

Primary source: Merrill Flood; Melvin Dresher

Adaptation

Changes in the structure, function, or behavior of living organisms act in increasing their adaptation to the environment.

Red Queen Effect

Species must continuously adapt and evolve to pass on genes to the next generation as well as to resist extinction when other opposing species are evolving. In the sequel to Alice's Adventures in Wonderland, the Red Queen said to Alice: Now, here you see, it takes all the running you can, to keep in the same place.

Primary source: Leigh Van Valen

Replication

The biochemical process of copying the DNA in a cell. It's a prerequisite for successful cell division since each daughter cell needs a complete set of DNA to function.

Hedonic Treadmill

People repeatedly return to their baseline level of happiness despite major positive or negative events or life changes. Expectations rise with results and the feeling of satisfaction is thus ever fleeting.

Primary source: Campbell Brickman

Self-Preservation

Pain and fear are integral parts of all living organisms, and self-preservation is the behavior that ensures their survival. Sigmund Freud proposed that self-preservation was one of two instincts that motivated human behavior, with the other being the sexual instinct. Later, he combined the two into eros.

It's interesting because self-preservation is not always in the heart. For instance, a mother might sacrifice her own life for her child.

Reward System

Also known as the pleasure center, organisms' reward center is made up of a group of neural structures that are responsible for incentive salience (the desire and craving for a reward), associative learning, and emotions such as joy, ecstasy, and euphoria. Sometimes, unhealthy addictions hijack our reward system if no discipline is exercised.

Exaptation

Evolution through natural selection allows traits that are originally meant for one purpose to enlist for a new main purpose.

Introduced by biologist Steven Jay Gould and Elisabeth Vrba, exaptation makes the point that a trait's current use does not necessarily explain its historical origin. Feathers are one example of a trait that has evolved through exaptation. First, they were meant for keeping warm or attracting mates. Later on, feathers became essential for modern birds' flight.

Primary source: Stephen Jay Gould; Elisabeth Vrba

Hormesis

Small doses of something can be good or beneficial for an individual but dangerous or deadly if applied at too large doses – e.g. alcohol or excessive exercise. It's when less is more.

Primary source: Hugo Schulz

Dunbar's Number

In the 1990s, anthropologist Robin Dunbar made a study on the correlation between primate brain size and average social group size. He found that it takes brainpower, specifically through the neocortex, to interact with other animals, to socialize and bond with them, and to remember past interactions. Dunbar then measured the human neocortex and estimated humans' ability to maintain social relationships, concluding that they can handle around 150 contacts.

Primary source: Robin Dunbar

Epidemic Models

Models used to study and predict epidemics of infectious diseases, with the most commonly known being the SIR model. In their simplest form, epidemic models assume that a disease has a given infection rate and a given removal rate. How the epidemic develops is always a function of these two factors.

While epidemic models are great at mostly explaining the spread of diseases in a biological setting, they are also great mental models for explaining how herd behavior can occur out of small inflections in various other domains. For example, using epidemic models to understand the transmission of attitude can be used to comprehend the feedback mechanisms that support speculative financial bubbles or religious/political propaganda.

Pollyanna Principle

It's easier to remember pleasant things than bad ones. Research indicates that the mind tends to focus on the optimistic at the subconscious level, while it tends to focus on the negative at the conscious level.

Declinism

The belief that society is heading towards a decline by putting a stronger emphasis on the negatives in accordance with the Pollyanna principle. One remembers the past as better than it was and expects the future to be worse than it will likely be.

Primary source: Edward Gibbon

Empathy Gap

Underestimating the way behavior is largely affected by one's mental state when an individual is not currently in that mental state. An individual currently feeling calm might find it difficult to predict how they will act if someone angers them.

Primary source: George Loewenstein

Meat Paradox

Socrates thought no one intentionally does anything morally wrong. However, individuals have the ability to adapt their attitude to action. For example, people care less about cows' well-being when they have just eaten beef jerky.

Primary source: George Loewenstein

Emotional Contagion

Empathy acts in transferring emotions from some individuals to others through observation. Happiness and misery love company.

Punctuated Equilibrium

Once species appear in the fossil record, they will become stable, showing little evolutionary change for most of their geological history.

Primary source: Niles Eldredge; Stephen Jay Gould

Luck Surface Area

Like emotional contagion, excitement and passion pull others into your orbit. Coined by Jason Roberts, he writes: The amount of serendipity that will occur in your life, your Luck Surface Area, is directly proportional to the degree to which you do something you're passionate about combined with the total number of people to whom this is effectively communicated. It's a simple concept, but an extremely powerful one because what it implies is that you can directly control the amount of luck you receive. In other words, you make your own luck.

Primary source: Jason Roberts

Tribalism

The division into or support for a tribe or tribes, especially policies characterized by tribal loyalty. In conformity, tribalism can refer to a way of thinking or behavior in which one is more loyal to one's tribe than to one's friends, one's country, or another social group.

Mental Models in the Physical World

Velocity

Velocity is a vector size that describes how far and in which direction something moves per unit of time. The size (length) of this vector is the scalar known as speed. Going one step forward and one step back shows no velocity but shows speed.

Relativity

The natural world allows no ruling frames of reference. When something is moving in a straight line at a constant speed with no acceleration, the laws of physics are the same for everyone. A man moving inside a train will not experience movement like an outside observer of the train would.

And because of matter, the faster you go, the heavier things become, and the more it will resist efforts to go faster. Albert Einstein proved that nothing that has a mass can ever reach the speed of light.

Primary source: Albert Einstein

Activation Energy

The energy needed to produce a certain reaction. The sparks that occur when steel is rubbed against flint provide the activation energy to initiate combustion in a Bunsen burner. The blue flame will sustain itself after the sparks have been extinguished because the continued combustion of the flame is now energetically favorable.

Primary source: Svante Arrhenius

Catalysts

A catalyst is a substance that increases the rate of a chemical reaction without itself being converted or consumed by the reaction. A catalyst is therefore involved in a reaction but is neither a reactant nor a product.

Leverage

Archimedes said: Give me a lever long enough and I shall move the world. Leverage is a very sensitive area since, depending on its application, its force might be incredibly powerful or incredibly devastating.

Read: [The Kelly Criterion Applied to Long-Term Value Investing](#)

Inertia

All things with a certain even rectilinear speed will continue to move in that direction until it is affected by an external force that causes it to either lose speed through negative acceleration (e.g. the braking effect in a car), increasing its speed through positive acceleration (e.g. giving a vehicle gas), or caused to change direction.

Consider a billiard ball that has just been pushed. Only when the ball strikes the band or another bullet does it change speed and direction under the influence of the force (reaction) that occurs at the encounter with the object it bumps into.

Primary source: Isaac Newton

Kinetics

A sub-area of technical mechanics that describes the change in movement quantities (location, speed, and acceleration) under the influence of forces and also takes into account the mass of the moving body. Kinematics, on the other hand, describes the movement of a body (location, speed, acceleration) without taking into account forces or masses.

Alloying

When a metal is combined with other substances, it can create a new metal with superior properties. The alloy may be stronger, harder, tougher, or more malleable than the original metal.

Viscosity

The inertia of a liquid, gas, or plasma – or its internal friction. Water is “thin” whereas honey is “thick”, which is why water has a lower viscosity than honey.

When measuring viscosity, the substances are divided into two groups: Newtonian and non-Newtonian fluids.

Newtonian fluids are homogeneous and viscosity is independent of how fast the liquid is stirred. Such fluids are defined by exact proportionality between the viscosity of the liquid and the tension it takes to make shifts in the liquid. Non-Newtonian fluids are heterogeneous and change viscosity as the rate of stirring changes. Rubbing resistance – or friction – is an expression of the force that pulls opposite of moving bodies and inhibiting movement.

Irreversibility

A concept arising frequently in thermodynamics, irreversibility means that the state of a system cannot be precisely restored to its initial state by infinitesimal changes in some property of the system without spending energy. Irreversible processes increase the entropy of the universe.

Primary source: Rudolf Clausius

Clark's Third Law

Any sufficiently advanced technology is indistinguishable from magic. And Clark's fourth law: For every expert, there is an equal and opposite expert.

Primary source: Arthur C. Clarke

Flywheel

A classic mechanical device that can retain kinetic energy in rotation over a shorter or longer period.

Another purpose of the flywheel is the gyroscope effect with an ability (tendency) of the rotating body to maintain a steady direction of its axis of rotation.

Primary source: James Watt

Half-Life

The time elapsed before an exponentially decreasing size is halved. The concept is mainly applied to decay processes that are exponential, e.g., radioactive decay, or approximately exponential such as biological decay.

Heisenberg Uncertainty Principle

Certain pairs of physical magnitudes cannot be determined with arbitrary accuracy. The more accurately one can measure the momentum (or velocity) of a particle, the less accurately one can know its position, and vice versa.

Primary source: Werner Heisenberg

Atomism

According to ancient atomism, the world is made up of countless small particles, atoms, separated by voids. Atoms differ in shape and size and cannot be perceived through senses. They constitute the basic substance of the world and are, as the name implies, indivisible. When atoms are combined in different formations, the physical objects that constitute the phenomena of the sensory world arise. From an initially unstructured state, the world evolves gradually as a result of the random movements of atoms. Any explanation is thus strictly mechanistic and materialistic.

Primary source: Leucippus

Autocatalysis

A chemical reaction in which an end product acts as a catalyst for the reaction. The continuous formation of this catalyst accelerates the reaction as long as sufficient starting materials are still available. It's a positive feedback loop.

Recursion

When something is defined in terms of itself. Recursion is used in a variety of disciplines, from linguistics to logic. The most common application is in mathematics and computer science, where a function is defined as applied to itself. Although this clearly defines an infinite number of instances (function values), it is often done in such a way that no loop or infinite chain of references can occur.

Electromagnetism

Electromagnetic force gives rise to most everyday phenomena, such as induction, friction, normal force (the force that prevents objects from flowing into each other), chemical reactions, and so on.

Primary source: Hans Christian Ørsted

Quantum Mechanics

A physical theory that describes the properties and laws of states and processes in matter. In contrast to the theories of classical physics, it allows the correct calculation of physical properties in the size of atoms and smaller.

Quantum mechanics forms the basis for describing the phenomena of atomic physics, solid-state physics, and nuclear and elementary particle physics, but also related sciences such as quantum chemistry.

Primary source: Werner Heisenberg

The Shannon-Hartley Law

A formula for calculating transmission capacity over any communication channel. The law provides the theoretical maximum that can be achieved with a hypothetical optimal channel coding, without providing information about which method can be used to achieve this optimum.

Primary source: Claude Shannon; Ralph Hartley

Mental Models in Military and War

Asymmetric War

A type of warfare in which two parties have different military capabilities or methods of war. In such a case, the weak party must take advantage of its special advantages or the opponent's weaknesses in order to have any opportunity to achieve its goals.

Attrition Warfare

A warfare where the warring parties are so strong that an end can only be reached through an extended and mutual depletion of each other's resources. The winner becomes the one with the largest reserves.

Two-Front War

Usually, parties prefer to fight on one front only since it makes it easier for them to concentrate on military efforts.

Another front usually arises when an ally intervenes in the war which means that both fronts will be weaker as it is more difficult to move forces from one front to another than moving them back and forth along a single front.

Choke Point

A small or narrow area that a larger number of soldiers cannot pass at the same time. They thus have a harder time attacking and can be more easily defeated by a less powerful enemy.

Counterinsurgency

As one of the more extensive areas of asymmetrical warfare, counterinsurgency describes various tactics and strategies used to combat armed insurgency. It's the blend of comprehensive civilian and military efforts designed to simultaneously contain insurgency and address its root causes.

Mutually Assured Destruction

A strategic doctrine originally formulated by Robert McNamara in response to the Cuban crisis of 1962. The doctrine implies that if one of two parties to a conflict uses its nuclear weapons, it results in the destruction of both parties. It is based on theories of terror balance, which argue that powerful weapons are essential in the effort to deter the enemy from using the same weapons. As a consequence of the doctrine, the warring parties had to point the weapons at the enemy's big cities.

Guerilla Warfare

Denotes an organized, armed struggle intended to influence or govern a state government. The states concerned will generally have an interest in classifying such movements as guerrilla movements. This implies that actions that are regarded as resistance struggles or freedom struggles on one side are regarded as armed rebellion and guerrilla movement on the other.

Fighting the Last War

The act of using strategies or tactics that worked successfully in the past, but are no longer useful.

Empty Fort Strategy

Contains elements of psychology and consists of convincing the opponent that an empty fortification is really full of hidden soldiers or traps which in turn induces the enemy to retreat.

Potemkin Village

A construction (literal or figurative) built solely to deceive others into thinking that a situation is better than it really is. It's named after the Russian prince Grigorij Potemkin who, before the emperor Catherine II's trip to Crimea in 1787, built theater decorations along her route depicting prosperous villages to give the impression that he had quickly achieved prosperity on the newly conquered peninsula.

Trojan Horse

A strategy in which a warring party is lured into letting in the enemy behind his defenses. Originally conceived by Odysseus.

Blitzkrieg

A strategy that is intended to prevent a conflict from escalating into total war and to achieve this through a rapid operational victory.

Primary source: Heinz Guderian

Decapitation

A massive strategic attack on the political and military leadership structures of the opponent with the intention of eliminating or at least significantly reducing its ability to counterattack.

Defeat in Detail

Bringing a large portion of one's own force to attack small enemy units in sequence, rather than engaging the bulk of the enemy force all at once.

Pincer Ambush

A strategy in which the opponent is enclosed by coordinated attacks around both flanks. If the military units carrying out the pincer ambush make contact with each other on the opposite side, the opponent is closed in and cannot retreat, but must strike out of the ring or get help from outside.

Shock and Awe

A strategy of using overwhelming power to try and achieve rapid dominance over the enemy.

Swarming

Use of a decentralized force against an opponent in a manner that emphasizes mobility, communication, unit autonomy, and coordination/synchronization.

Turning Movement

A strategy that allows an attacking force to reach the opposing rear guard by separating the defenders from their main defensive positions.

Win Without Fighting

Sun Tzu argued that a brilliant general was one that could win without killing anybody.

Defense in Depth

A strategy in which the defending side places its units so that they gradually absorb the strength of an attacking enemy.

Fortification

A semi-permanent or permanent defensive structure that gives physical protection to a military unit.

Fabian Strategy

A strategy that aims to avoid field battles and frontal attacks by wearing out the opponent instead, e.g. through disruptions in logistics or by affecting morale. Used by warring parties who have time on their side or when there is no other alternative.

Primary source: George Washington

Scorched Earth

A tactic that consists of destroying buildings, factories, fields, and the like during a retreat. The purpose is to prevent them from falling into the hands of the enemy and thus contributing to its resources.

Turtling

Continuous reinforcement of the military front until it has reached its full strength followed by an attack with the now-superior force.

Mental Models in Political Failure

Chilling Effect

The reluctance or unwillingness to exercise one's right due to fear of legal sanctions. A common example is that of free speech.

Primary source: John Milton

Third Rail of Politics

A metaphor for any subject so controversial that it is "untouchable" in the measure that any politician or public official who dares to approach the subject, invariably suffers politically.

Primary source: Kirk O'Donnell

Regulatory Capture

A form of political corruption that occurs when a government body, rather than acting in the interests of society, represents the commercial or special interests of a particular interest group (lobby) that dominates the industry or sector.

Primary source: George Stigler

State Capture

A type of systemic political corruption in which private interests significantly influence a state's decision-making processes to its advantage.

Shirky Principle

Institutions will try to preserve the problem to which they are the solution.

Primary source: Clay Shirky

Mental Models in Rule of Law

Burden of Proof

A party's obligation to present evidence of a claim in a conflict.

Common Law

Legal systems characterized by the fact that courts have legislative function in the sense that they have the opportunity not only to interpret law but also create it through precedents.

Precedents

Prior judgments, decisions, or rulings in a court of law used as a rule or guide in later cases or cases with similar circumstances.

Due Process

A procedural legal principle according to which everyone has the right to certain minimum guarantees, aimed at ensuring a fair and equitable result in the process.

Duty of Care

An obligation to pay certain attention and reasonable care required by law while performing any acts that could foreseeably harm others.

Good Faith

Also called bona fides, it denotes a party's excusable ignorance of a particular relationship. What matters in this context is an assessment of what a sensible person would have done in the same concrete situation.

Negligence

When something is caused by carelessness amongst specified circumstances.

Presumption of Innocence

The basic principle of criminal procedure that gives the person suspected of a crime the right to be regarded as innocent until the contrary has been proved. The principle is considered so important that many democracies have explicitly stated it in their laws or constitutions.

Reasonable Doubt

Evidence that is beyond reasonable doubt is the standard of evidence required to validate a criminal conviction in most prosecution systems.

Mental Models in other things

Return on investment

Return on investment is a powerful mental model for decision-making in real life. Here are some real-life examples of ROI in action. "**Should I make a financial investment?**" ROI calculations are a hallmark of actual investing. The objective of an investment is to secure a return; there's no point investing and risking your money unless there's a benefit.

Synergy and systems

Synergy is when a combination of companies, talents, or ideas creates **more value** than the sum of them alone.

Google's YouTube acquisition is a good example.

It gave YouTube enormous resources to deal with challenges. And Google a social platform as a new advertising channel.

The **synergy** between Google and YouTube didn't create value only for them. Today 2.6 billion people use it for entertainment or to learn anything they want. And millions of creators earn their living from YouTube.

Yin-yang effect

Yin-Yang celebrates duality. Opposites are needed to sustain and balance each other. Just like we need to balance risk and opportunity for innovation to thrive, a correct balance between different workspaces will help us become more productive and find the right work-life balance.

Iterative cycles

Iterative (agile) life cycles are composed of several iterations, which repeat one or more of the phases before proceeding to the next one. Iterative approaches can only proceed when user feedback is available to be used as the basis for initiating new cycles of development, refinement and improvement.

Feedback loop.

Feedback loops are typically used to accomplish regulation and control. A feedback loop is like an input, but its origin is from within the system itself, not from outside the system. In many systems, the output reenters the system as another input.

Galilean relativity

Galilean relativity, if Newton's laws are true in any reference frame, they are also true in any other frame moving at constant velocity with respect to the first one.

Pattern Interrupt

Originating from neuro-linguistic programming, pattern interrupt involves recognizing an unwanted pattern, disrupting it, and leading someone to the desired behavior.

Psychologists use pattern interrupts to break people out of unwanted or unconscious responses they've developed throughout a lifetime.

Loss Aversion

The pain of losing is twice as immense as the pleasure of gaining. We tend to avoid losses over earning gains. This can lead to an overly conservative portfolio that does not deliver the returns needed for an investor to achieve their financial goals.

Mean Reversion

Most things revert to the mean. In investing, this usually refers to profitability, growth & valuation. If an industry is high profitability, it'll start attracting competition. Unless there's an economic moat, excess profits will be competed away.

Economic Moat

A strong economic moat exists when there's a long-term competitive advantage. Moat protects a company's profitability and growth from competition. Examples:

- High switching costs
- Economies of scale
- Network effects
- Regulations
- Branding

Luck Skill Continuum

Unlike chess, investing is more like a game of poker. Success in investing is partially determined by luck. A good outcome may be the result of either a good or bad process. Evaluate your investments by your process, and less on outcomes.

The 5/25 Rule

List the 25 things you want to achieve.

Decide on the 5 most important ones from the list.

Now you have 5 goals that you'll focus on this year.

What will you do with the rest?

You'll **avoid them** at all costs until you achieve the 5 first. Because they are distractions that will stop you from achieving your priorities.

Lateral Thinking

Sometimes, logic becomes a burden to find the right solution to complex problems. Because it limits us to **logical constraints** before we discover all other possibilities. Lateral thinking forces you to break the barriers that limit your creativity. Like asking “*What would Napoleon do?*” to solve a business problem.

Compartmentalization

Napoleon’s secret to handling many complex topics with full attention. It’s not multitasking; it’s extreme **unitasking**. To use it, give your full attention to one single task (or project) every time. Never multitask.

Input Goals

Most of the goals you set are output goals, based on outcomes (becoming a millionaire or getting a six-pack). But the outcomes are never under your control. Focus on input goals to achieve your goals.

Information Arbitrage

Everybody has specific knowledge that they can leverage by trading it. Information Arbitrage is benefiting from the knowledge gap between you and others. Observe people, companies, and sectors to find where your skills are **more valuable**. As an example, Facebook/Google Ads knowledge is common for digital businesses. But many physical businesses lack this knowledge, which creates an information arbitrage **opportunity**.

Leverage

Leverage —as a concept— is getting the maximum output with the same input. Money, labor, code, and media are forms of leverage. You can write 300 words on a paper (low leverage) or on a blog (high leverage). If you publish it on a blog, millions of people can read it **without any additional effort** from you. So use it as a filter to amplify your impact. Simple example: If you keep receiving the same questions from your customers or followers; don’t answer them one by one. Either create a product or an FAQ

The Snowball Effect

The power of compounding. Money, effort, and knowledge compound in the long term in ways you cannot imagine. Many people don’t get the benefits from the snowball effect as they’re impatient and interrupt the snowball’s momentum.

Talent Stacking

Talent stacking is increasing your chances of success by becoming good at many skills, rather than trying to become the best at one. Because becoming the best at **one thing** is *almost* impossible. While becoming good at different skills is an easier way to extraordinary success. One example is Alexandra Botez. She is a good chess player, entertainer, and social media creator. But she is not the best at any of them.

Optionality

An *option* in life is having the right, but not the obligation, to perform an action.

And **optionality** is having many *options* to choose from.

But a good option should have **asymmetry** between its cost and potential benefit. The bigger the asymmetry is, the better the option.

So with optionality, the idea is to have more options with low cost, but unlimited upside.

As an example, writing online has more optionality than keeping a private journal. It has the same cost, but unlimited upside potential if people like what you write about.

Picasso's Bull

Hundreds of discarded ideas and prototypes allowed the Apple team to come up with the iPhone.

Thousands of iterations and paintings made Picasso one of the best painters of history.

Picasso's Bull shows us the **power of iteration**.

Whatever you'd like to achieve in life, the path to success is the same: *Quantity* brings **quality**.

The Pygmalion Effect

Pygmalion Effect is when higher expectations lead to better performance.

Because they affect others' actions toward you, hence your beliefs about yourself, and your actions toward others.

It's a **self-fulfilling prophecy**.

So have higher expectations from people around you, and make sure they are aware of your expectations.

Personal SWOT Analysis

SWOT Analysis is a tool that executives use to have situational awareness of their companies: strengths, weaknesses, opportunities, and threats.

Personal SWOT analysis makes you reflect on your life as you haven't done before.

It paints a picture of your current situation, so you can find the best path for yourself.

Control the Centre

Controlling 4 squares in the middle of the chess board has massive advantage, as the piece in the middle has maximum influence. High ground is important as this gives more reach, not necessarily exposing to more risks. Where is the centre of the board. What do I need to do to get pieces there so that they have maximum influence? This mental model gives you strategic thinking, and allows you to see where you should be focusing at any given moment.

The true value of Piece

All pieces in chess have different values. The true pieces worth is truly shown in the board dynamic. If you're struggling with the problem, like weight loss, then a question often asked is how should I solve this. The better question is who do I know to help me to solve this.

Position over submission

Whoever has more powerful army on chess this is winning. However, smaller army occupying better terrain, can hold off more powerful army. Like in Brazilian jiu-jitsu, the lower belt trying to submit you by trying quick submit, but the higher belts are trying to dominate position, before submitting. What does it mean to control the position here? don't just go for the ending move, first get the upper hand.

Owning The Initiative

Determining in chess who is dictating the action. Which player is acting and which player is reacting. Object in motion stays in motion. Get momentum (activation energy (high) --> maintenance energy (low))

The hardest move to Find (Tactical retreat).

Tactical retreat (sometimes the best move is to take a step back, sometimes the only way to move forward is to take a step back).

Swiss Army knife approach

You need to learn multiple things how to drive a car, like steering wheel, clutch, breaks etc. If you want to be successful in the world, you need to learn many different ideas. Few if the models carry most of the freight. Charles Munger stated: by the definition where you going to play with multiple techniques and multiple models, and the a lot of experience is very helpful. Be like a man with Swiss army knife, realised that different problems requires different tools and applies the best tool for given situation.

Anchoring: a cognitive bias where an individual relies too heavily on an initial piece of information—the “anchor”—when making decisions.

Backward chaining: working backward from your goal.

Classical conditioning: you've probably heard about Pavlov's dog. Classical conditioning is a learning method in which a biologically potent stimulus—such as food—is paired with a previously neutral stimulus—let's say a bell. The neutral stimulus comes to create a response (salivation) that is usually similar to the one created by the potent stimulus (in this case, food).

Commitment and consistency bias: the desire to be and appear consistent with what we have already done.

Common knowledge: knowledge that is known by everyone or nearly everyone, usually with reference to a particular community. Common knowledge doesn't necessarily mean truth, but most people will accept it as valid.

Comparative advantage: the ability to carry out a particular economic activity—such as making a specific product—more efficiently than another activity.

Diversification: the process of allocating your resources in a way that reduces the exposure to any one particular risk.

Economies of scale: the cost advantages that businesses obtain due to their scale of operation. The larger the scale, the smaller the cost per unit.

Efficient-market hypothesis: a theory that states that prices fully reflect all available information. The hypothesis implies that it should be impossible to consistently beat the market, since market prices should only react to new information.

Game theory: an umbrella term for the science of logical decision making in humans, animals, and computers.

Hyperbolic discounting: a model which states that, given two similar rewards, people show a preference for one that arrives sooner rather than later.

Illusion of control: the tendency for people to overestimate their ability to control events.

Incentive: something that motivates or encourages someone to do something.

Inversion principle: the process of looking at a problem backward. For example, instead of brainstorming forward ideas, imagine everything that could make your project go terribly wrong.

Loss aversion: people's tendency to prefer avoiding losses to acquiring equivalent gains. We are basically more upset about losing \$10 than we are happy about finding \$10

Margin of safety: in a business, how much sales level can fall before a company reaches its break-even point.

The sailboat metaphor: a dynamic model of human needs devised by Scott Barry Kaufman, such as physiological needs, safety needs, love and belonging, esteem, and self-actualisation.

Mechanical advantage: also called the *law of the lever*, it's a measure of how much your strength is amplified by using a tool or mechanical device.

Mere-exposure effect: a psychological phenomenon by which people tend to develop a preference for things merely because they are familiar with them.

Norm of reciprocity: the expectation that we repay in kind what another has done for us.

Normal distribution: a theory which states that averages of samples of observations of random variables become normally distributed when the number of observations is sufficiently large.

Operant conditioning: a learning process where the strength of a behaviour is modified by reinforcement or punishment.

Redundancy: the duplication of critical components of a system with the intention of increasing its reliability. For example, a backup or a fail-safe.

Scarcity: the limited availability of a commodity, which may be in demand in the market. Basically, when something is in short supply.

Signalling theory: the science of determining whether people with conflicting interests should be expected to provide honest signals rather than cheating.

Status quo bias: a preference for the current state of affairs, where the current baseline is taken as a reference point, and any change from that baseline is perceived as a loss.

Supply and demand: an economic model which postulates that, in a competitive market, the unit price for a particular good or service will vary until it settles at a point where the quantity demanded will equal the quantity supplied, resulting in an equilibrium for price and quantity transacted.

Surfing: the business principle of “riding the wave” of a new technology, product, or trend.

Survivorship bias: the logical error of concentrating on the people that made it past some selection process and overlooking those that did not, typically because of their lack of visibility. Happens a lot in entrepreneurship.

Tribalism: a way of thinking in which people are loyal to their social group above all else. Creating a detailed expansion for each mental model would be quite lengthy, but I can provide a brief explanation for each one:

1. **Occam's Razor:** This principle states that among competing hypotheses, the one with the fewest assumptions should be selected. In essence, it encourages simplicity and parsimony in explanations.
2. **Pareto Principle (80/20 Rule):** This principle suggests that roughly 80% of effects come from 20% of causes. It's commonly used to prioritize efforts, focusing on the most significant factors that yield the greatest results.
3. **Inversion:** Inversion involves solving problems by considering the opposite or reversing the problem statement. By thinking about what you want to avoid, you can often uncover solutions more effectively.
4. **First Principles Thinking:** This approach involves breaking down complex problems into fundamental truths or principles and then building solutions from the ground up. It encourages independent thinking and innovation.
5. **Circle of Competence:** This model suggests that individuals should focus on areas within their expertise or knowledge. By staying within their circle of competence, individuals can make better-informed decisions and avoid unnecessary risks.
6. **Confirmation Bias:** This cognitive bias refers to the tendency to seek out information that confirms existing beliefs or opinions while ignoring or dismissing contradictory evidence.
7. **Availability Heuristic:** This heuristic involves making judgments based on how easily relevant examples or instances come to mind. It can lead to biases in decision-making, as vivid or recent events may be overemphasized.

8. **Anchoring Bias:** Anchoring bias occurs when individuals rely too heavily on initial information (the "anchor") when making subsequent judgments or decisions, even if the anchor is irrelevant or misleading.
9. **Loss Aversion:** Loss aversion refers to the tendency for individuals to prefer avoiding losses over acquiring equivalent gains. It can influence decision-making by causing people to take risks to avoid losses.
10. **Sunk Cost Fallacy:** This fallacy occurs when individuals continue investing resources (time, money, etc.) into a project or endeavor simply because they've already invested heavily in it, despite diminishing returns or future costs outweighing benefits.

These are just brief explanations to get started. Each mental model has rich implications and applications across various contexts, so diving deeper into each one can yield valuable insights for decision-making and problem-solving.

11. Match Mental model or mental models to factors.

Evaluate each potential mental model against the identified factors of the problem or situation. Consider how well each mental model aligns with the complexities and nuances of the issue you're addressing. Some mental models may be more applicable to certain types of problems or contexts than other.

12. Using Mental Models to Stay Calm In Charged Situations.

When polarizing topics are discussed in meetings, passions can run high and cloud our judgment. Learn how mental models can help you see clearly from this real-life scenario.

Mental models can sometimes come off as an abstract concept. They are, however, actual tools you can use to navigate through challenging or confusing situations. In this article, we are going to apply our mental models to a common situation: a meeting with conflict. A recent meeting with the school gave us an opportunity to use our latticework. Anyone with school-age kids has dealt with the bureaucracy of a school system and the other parents who interact with it. Call it what you will, all school environments usually have some formal interface between parents and the school administration that is aimed at progressing issues and ideas of importance to the school community.

The particular meeting was an intense one. At issue was the school's communication around a potentially harmful leak in the heating system. Some parents felt the school had communicated reasonably about the problem and the potential consequences. Others felt their child's life had been put in danger due to potential exposure to mold and asbestos. Some parents felt the school could have done a better job of soliciting feedback from students about their experiences during the previous week, and others felt the school administration had done a poor job about communicating potential risks to parents. The first thing you'll notice if you're in a meeting like this is that emotions on all sides run high. After some discussion you might also notice a few more things, like how many people do the following:

- Confuse correlation with causation in determining why certain things happened
- Extrapolate from too small a sample size when providing "evidence" to prove their point
- Don't recognize hindsight bias when suggesting what should have been done
- Don't pay attention to base rates when assessing the severity of events
- Assume maliciousness on the part of decision-makers

Any of these occurrences, when you hear them via statements from people around the table, are a great indication that using a few mental models might improve the dynamics of the situation.

The first mental model that is invaluable in situations like this is Hanlon's Razor: don't attribute to maliciousness that which is more easily explained by incompetence. (Hanlon's Razor is one of the 9 general thinking concepts in The Great Mental Models Volume One.) When people feel victimized, they can get angry and lash out in an attempt to fight back against a perceived threat. When people feel accused of serious wrongdoing, they can get defensive and withhold information to protect themselves. Neither of these reactions is useful in a situation like this. Yes, sometimes people intentionally do bad things. But more often than not, bad things are the result of incompetence. In a school meeting situation, it's safe to assume everyone at the table has the best interests of the students at heart.

School staff and administrators usually go into teaching motivated by a deep love of education. They genuinely want their schools to be amazing places of learning, and they devote time and attention to improving the lives of their students.

It makes no sense to assume a school's administration would deliberately withhold harmful information. Yes, it could happen. But, in either case, you are going to obtain more valuable information if you assume poor decisions were the result of incompetence versus maliciousness.

When we feel people are malicious toward us, we instinctively become a negatively coiled spring, waiting for the right moment to take them down a notch or two. Removing malice from the equation, you give yourself emotional breathing room to work toward better solutions and apply more models.

The next helpful model is relativity, adapted from the laws of physics. This model is about remembering that everyone's perspective is different from yours. Understanding how others see the same situation can help you move toward a more meaningful dialogue with the people in the meeting. You can do this by looking around the room and asking yourself what is influencing people's approaches to the situation.

In our school meeting, we see some people are afraid for their child's health. Others are influenced by past dealings with the school administration. Authorities are worried about closing the school. Teachers are concerned about how missed time might impact their students' learning. Administrators are trying to balance the needs of parents with their responsibility to follow the necessary procedures. Some parents are stressed because they don't have care for their children when the school closes. There is a lot going on, and relativity gives us a lens to try to identify the dynamics impacting communication.

After understanding the different perspectives, it becomes easier to incorporate them into your thinking. You can diffuse conflict by identifying what it is you think you hear. Often, just the feeling of being heard will help people start to listen and engage more objectively. Now you can dive into some of the details. First up is probabilistic thinking. Before we worry about mold levels or sick children, let's try to identify the base rates. What is the mold content in the air outside? How many children are typically absent due to sickness at this time of year? Reminding people that severity has to be evaluated *against* something in a situation like this can really help diffuse stress and concern. If 10% of the student population is absent on any given day, and in the week leading up to these events 12% to 13% of the population was absent, then it turns out we are not actually dealing with a huge statistical anomaly.

Then you can evaluate the anecdotes with the model of the Law of Large Numbers in mind. Small sample sizes can be misleading. The larger your group for evaluation, the more relevant the conclusions. In a situation such as our school council meeting, small sample sizes only serve to ratchet up the emotion by implying they are the causal outcomes of recent events.

In reality, any one-off occurrence can often be explained in multiple ways. One or two children coming home with hives? There are a dozen reasonable explanations for that: allergies, dry skin, reaction to skin cream, symptom of an illness unrelated to the school environment, and so on. However, the more children that develop hives, the more it is statistically possible the cause relates to the only common denominator between all children: the school environment.

Even then, correlation does not equal causation. It might not be a recent leaky steam pipe; is it exam time? Are there other stressors in the culture? Other contaminants in the environment? The larger your sample size, the more likely you will obtain relevant information.

Finally, you can practice systems thinking and contribute to the discussion by identifying the other components in the system you are all dealing with. After all, a school council is just one part of a much larger system involving governments, school boards, legislators,

administrators, teachers, students, parents, and the community. When you put your meeting into the bigger context of the entire system, you can identify the feedback loops: Who is responding to what information, and how quickly does their behavior change? When you do this, you can start to suggest some possible steps and solutions to remedy the situation and improve interactions going forward.

How is the information flowing? How fast does it move? How much time does each recipient have to adjust before receiving more information? Chances are, you aren't going to know all this at the meeting. So you can ask questions. Does the principal have to get approval from the school board before sending out communications involving risk to students? Can teachers communicate directly with parents? What are the conditions for communicating possible risk? Will speculation increase the speed of a self-reinforcing feedback loop causing panic? What do parents need to know to make an informed decision about the welfare of their child? What does the school need to know to make an informed decision about the welfare of their students?

In meetings like the one described here, there is no doubt that communication is important. Using the meeting to discuss and debate ways of improving communication so that outcomes are generally better in the future is a valuable use of time.

A school meeting is one practical example of how having a latticework of mental models can be useful. Using mental models can help you diffuse some of the emotions that create an unproductive dynamic. They can also help you bring forward valuable, relevant information to assist the different parties in improving their decision-making process going forward.

At the very least, you will walk away from the meeting with a much better understanding of how the world works, and you will have gained some strategies you can implement in the future to leverage this knowledge instead of fighting against it.

- 13. Assess Suitability and Effectiveness:** Assess the suitability and effectiveness of each candidate mental model. Consider whether the mental model provides useful insights, helps simplify complexity, or offers actionable guidance. Additionally, think about whether the mental model aligns with your cognitive style and preferences.
- 14. Select the Most Appropriate Model:** Based on your assessment, choose the mental model that best fits the problem or situation you're facing. Keep in mind that you may need to adapt or combine multiple mental models to address different aspects of complex problems.
- 15. Apply and Evaluate:** Apply the selected mental model to analyze the problem or situation. Pay attention to the insights gained and the impact on your decision-making process. Afterward, evaluate the effectiveness of the chosen mental model in helping you achieve your objectives.
- 16. Iterate and Learn:** If the selected mental model doesn't yield the desired results, don't hesitate to iterate and try a different approach. Learning from your experiences will enhance your ability to select and apply mental models effectively in the future.

Step 77-Charles Munger Look at the world

Charles Munger, the Vice Chairman of Berkshire Hathaway and Warren Buffett's longtime business partner, is known for his multidisciplinary approach to decision-making and problem-solving. Munger has often emphasized the importance of mental models in achieving success in various endeavors. Let's explore some of the mental models Charles Munger has advocated for and their expansions:

1. **Elementary Worldly Wisdom:** Munger emphasizes the importance of cultivating a broad understanding of various disciplines, including psychology, economics, and physics. By acquiring a diverse toolkit of mental models from different fields, individuals can make more informed decisions and anticipate consequences across a wide range of situations.
2. **Inversion:** Munger frequently employs the principle of inversion, which involves considering the opposite of what you want to achieve. By identifying and avoiding potential pitfalls or obstacles, individuals can enhance their decision-making and problem-solving abilities. Inversion encourages a proactive approach to risk management and planning.
3. **Circle of Competence:** Munger stresses the importance of staying within one's circle of competence—the areas where one has expertise or deep understanding. By focusing on what you know and understand well, you can make more accurate judgments and avoid costly mistakes. Munger advises against venturing into unfamiliar territory without thorough research and understanding.

4. **Latticework of Mental Models:** Munger advocates for building a latticework of mental models—a network of interconnected concepts and principles from various disciplines. By integrating insights from diverse sources, individuals can develop a more robust framework for understanding complex systems and making sound decisions. This approach encourages continuous learning and synthesis of new ideas.
5. **Psychology and Human Behavior:** Munger emphasizes the importance of understanding human psychology and behavior in decision-making. He acknowledges the role of cognitive biases, such as confirmation bias and overconfidence, in shaping our judgments and actions. By being aware of these biases, individuals can mitigate their effects and make more rational choices.
6. **Incentives and Disincentives:** Munger recognizes the power of incentives and disincentives in shaping human behavior and organizational dynamics. He advocates for aligning incentives with desired outcomes to encourage positive behavior and discourage undesirable actions. Understanding the underlying motivations of individuals and stakeholders is essential for designing effective incentive structures.
7. **Margin of Safety:** Munger stresses the importance of incorporating a margin of safety—a buffer or cushion—into decision-making processes. Whether investing in stocks or making business decisions, having a margin of safety provides protection against unforeseen risks and uncertainties. It allows individuals to withstand adverse conditions and capitalize on opportunities that may arise.
8. **Multidisciplinary Thinking:** Munger encourages multidisciplinary thinking—the ability to draw insights from various disciplines and apply them to different contexts. By embracing diverse perspectives and approaches, individuals can uncover innovative solutions and gain a competitive edge.

Multidisciplinary thinking fosters creativity, adaptability, and resilience in the face of complexity.

9. **Long-Term Perspective:** Munger advocates for adopting a long-term perspective in decision-making and investing. Instead of focusing solely on short-term gains, he emphasizes the importance of considering the enduring value and sustainability of investments and initiatives. Taking a long-term view encourages patience, discipline, and strategic thinking.
10. **Continuous Learning and Adaptation:** Munger underscores the value of continuous learning and adaptation in an ever-changing world. He encourages individuals to embrace intellectual curiosity, humility, and a willingness to update their beliefs in light of new evidence. By remaining open-minded and flexible, individuals can stay ahead of the curve and thrive in dynamic environments.

Step Multidisciplinary, Interdisciplinary, transdisciplinary

Applying a latticework of mental models involves integrating various mental models into your thinking and decision-making processes. Here's how you can do it:

1. **Familiarize Yourself with Mental Models:** Start by learning about different mental models from various disciplines such as psychology, economics, biology, and physics. Understand the underlying principles and how they can be applied to different situations.
2. **Identify Relevant Mental Models:** Consider the specific challenges or decisions you're facing and identify which mental models might be most relevant. For example, if you're trying to understand a complex problem, systems thinking or probabilistic thinking might be useful.
3. **Analyze from Multiple Perspectives:** Instead of relying on a single mental model, analyze situations from multiple perspectives by applying different mental models. This helps you gain a more comprehensive understanding and uncover insights that might not be apparent from a single viewpoint.
4. **Synthesize Insights:** Look for patterns, connections, and relationships between different mental models. Synthesize insights from various models to develop a more nuanced understanding of the problem or situation at hand.
5. **Test and Validate Assumptions:** Use mental models to test and validate assumptions underlying your thinking or decisions. Challenge your beliefs and consider alternative explanations or scenarios.
6. **Apply Mental Models Holistically:** Integrate mental models into your decision-making process holistically rather than applying them in isolation. Consider how different models interact and complement each other to inform your actions.

7. **Practice Mental Model Flexibility:** Be flexible in your application of mental models and adapt them to different contexts or situations. What works in one scenario may not work in another, so be open to adjusting your approach accordingly.
8. **Reflect and Learn:** After applying mental models, reflect on the outcomes and lessons learned. Consider how effective the models were in helping you understand and address the problem, and identify opportunities for improvement.
9. **Continuous Learning and Iteration:** Cultivate a mindset of continuous learning and iteration by constantly seeking new mental models, refining your understanding, and updating your thinking based on new insights and experiences.
10. **Share and Collaborate:** Share your knowledge of mental models with others and collaborate with them to apply them in various contexts. Engaging in discussions and exchanging perspectives can enrich your understanding and enhance your ability to apply mental models effectively.

By following these steps, you can build a robust latticework of mental models that enables you to approach problems and make decisions with greater clarity, depth, and effectiveness.

Applying multidisciplinary thinking involves integrating knowledge and perspectives from multiple disciplines to solve complex problems and generate innovative solutions. Here's a step-by-step guide:

1. **Identify the Problem or Challenge:** Clearly define the problem or challenge you're facing. Break it down into its component parts and consider the various factors contributing to it.
2. **Gather Information from Different Disciplines:** Research and gather information from diverse disciplines that are relevant to the problem or challenge. This may include fields such as psychology, economics, biology, sociology, engineering, and more.
3. **Understand Core Concepts and Principles:** Develop a basic understanding of the core concepts and principles from each discipline. This will help you identify key insights and connections between different areas of knowledge.

4. **Analyze Interconnections and Interdependencies:** Explore how concepts and principles from different disciplines intersect and influence each other in relation to the problem or challenge at hand. Look for patterns, relationships, and potential causal mechanisms.
5. **Synthesize Insights and Perspectives:** Integrate insights and perspectives from multiple disciplines to develop a holistic understanding of the problem or challenge. Consider how different factors interact and contribute to the overall complexity of the situation.
6. **Identify Opportunities for Innovation:** Use multidisciplinary thinking to identify new opportunities for innovation and creative problem-solving. Look for unconventional approaches or solutions that leverage insights from different disciplines.
7. **Evaluate Risks and Trade-offs:** Assess the potential risks and trade-offs associated with different approaches or solutions. Consider the implications from various perspectives, including ethical, social, economic, and environmental considerations.
8. **Develop and Test Solutions:** Generate potential solutions based on your multidisciplinary analysis and insights. Test these solutions through experimentation, prototyping, or simulation to evaluate their feasibility and effectiveness.
9. **Iterate and Refine:** Iterate on your solutions based on feedback and new information. Continuously refine your approach by incorporating insights from ongoing learning and reflection.
10. **Communicate and Collaborate:** Communicate your findings and recommendations effectively to stakeholders from diverse backgrounds. Collaborate with experts from different disciplines to leverage their expertise and perspectives in refining and implementing solutions.
11. **Reflect and Learn:** Reflect on your multidisciplinary thinking process and outcomes. Identify lessons learned and areas for improvement to enhance your ability to apply this approach in future challenges.

By following these steps, you can leverage the power of multidisciplinary thinking to tackle complex problems, drive innovation, and create value in various domains.

Sure, let's break down each approach and provide comprehensive steps for applying them:

Multidisciplinarity:

1. **Identify the Problem:** Clearly define the problem or topic you want to address, considering its complexity and potential intersection with multiple disciplines.
2. **Identify Relevant Disciplines:** Determine which disciplines are likely to provide valuable insights or perspectives on the problem. This may involve fields such as psychology, economics, biology, sociology, etc.
3. **Engage Experts from Different Disciplines:** Collaborate with experts from the identified disciplines to gather diverse perspectives and insights. Encourage open communication and knowledge-sharing among team members.
4. **Analyze Insights from Each Discipline:** Analyze the contributions from each discipline to identify common themes, patterns, or contradictions. Look for opportunities to integrate different perspectives into a cohesive understanding of the problem.
5. **Synthesize Findings:** Synthesize the insights and findings from each discipline to develop a comprehensive understanding of the problem. Identify connections, interdependencies, and potential solutions that emerge from the multidisciplinary analysis.
6. **Develop Solutions or Recommendations:** Based on the synthesized findings, develop solutions or recommendations that leverage insights from multiple disciplines. Consider the feasibility, effectiveness, and ethical implications of proposed solutions.
7. **Communicate and Collaborate:** Communicate the multidisciplinary findings and recommendations effectively to stakeholders, policymakers, or relevant audiences. Collaborate with stakeholders to refine and implement solutions in a collaborative manner.

Interdisciplinarity:

1. **Define the Research Question or Problem:** Clearly articulate the research question or problem that requires an interdisciplinary approach. Ensure that it involves aspects that cannot be adequately addressed within a single discipline.
2. **Identify Relevant Disciplines and Perspectives:** Identify the disciplines and perspectives that are necessary to address the research

question comprehensively. This may involve conducting a literature review or consulting with experts from different fields.

3. **Establish a Collaborative Team:** Assemble a collaborative team of researchers or experts from the identified disciplines. Ensure diversity in expertise, backgrounds, and perspectives within the team.
4. **Integrate Disciplinary Insights:** Facilitate open dialogue and knowledge exchange among team members to integrate insights from different disciplines. Encourage interdisciplinary collaboration and brainstorming sessions to generate novel ideas and approaches.
5. **Develop an Integrative Framework or Model:** Develop an integrative framework or model that synthesizes insights from the various disciplines involved. This framework should provide a holistic understanding of the research question and guide subsequent analysis and interpretation.
6. **Collect and Analyze Data:** Collect data from relevant sources using interdisciplinary methods and approaches. Analyze the data using appropriate techniques that account for the complexity and diversity of disciplinary perspectives.
7. **Interpret Findings and Draw Conclusions:** Interpret the findings within the context of the integrative framework, considering the interactions and interdependencies between different factors. Draw conclusions that reflect the multidimensional nature of the research question.
8. **Communicate Results:** Communicate the interdisciplinary findings and implications effectively to academic audiences, practitioners, policymakers, or other stakeholders. Use clear and accessible language to convey complex ideas and facilitate understanding across disciplinary boundaries.

Transdisciplinarity:

1. **Identify a Complex Social or Environmental Issue:** Select a complex social or environmental issue that transcends disciplinary boundaries and requires collaboration between academia, practitioners, and stakeholders.
2. **Form a Transdisciplinary Team:** Form a transdisciplinary team comprising researchers, practitioners, policymakers, and

representatives from affected communities or stakeholders. Ensure diverse perspectives, expertise, and experiences within the team.

3. **Define Shared Goals and Objectives:** Establish shared goals and objectives that reflect the common interests and aspirations of all stakeholders involved. Foster a shared sense of purpose and commitment to addressing the issue collaboratively.
4. **Engage in Reflexive Dialogue and Knowledge Integration:** Facilitate reflexive dialogue and knowledge integration among team members to explore diverse perspectives, assumptions, and values. Emphasize mutual learning and co-production of knowledge throughout the process.
5. **Co-design and Co-implement Interventions:** Co-design and co-implement interventions or strategies that address the root causes of the issue and promote sustainable solutions. Involve stakeholders in decision-making and action planning to ensure relevance and ownership.
6. **Monitor and Evaluate Impact:** Continuously monitor and evaluate the impact of interventions on the issue and the broader system. Use participatory and adaptive evaluation approaches to engage stakeholders in ongoing learning and improvement.
7. **Reflect and Adapt:** Reflect on the transdisciplinary process and outcomes to identify lessons learned and areas for improvement. Adapt the approach and strategies based on feedback and evolving understanding of the issue and context.
8. **Share Insights and Lessons Learned:** Share insights, best practices, and lessons learned from the transdisciplinary process with other stakeholders, organizations, and communities. Contribute to collective learning and capacity-building efforts to address similar issues in different contexts.

By following these comprehensive steps, you can effectively apply multidisciplinary, interdisciplinarity, and transdisciplinarity to tackle complex problems and promote sustainable solutions that integrate diverse perspectives and expertise.

Certainly! Integrating mental models into multidisciplinary, interdisciplinary, and transdisciplinary approaches can enhance problem-solving, decision-making, and knowledge integration across disciplines. Here are comprehensive steps for each approach:

Multidisciplinary with Mental Models:

1. **Identify the Problem:** Define the problem or topic requiring a multidisciplinary approach, considering its complexity and potential intersections with various disciplines.
2. **Select Relevant Mental Models:** Identify relevant mental models that can provide insights into different aspects of the problem. Choose models from psychology, economics, sociology, biology, etc., based on their applicability.
3. **Engage Experts from Different Disciplines:** Collaborate with experts from relevant disciplines and introduce them to the selected mental models. Facilitate discussions to explore how these models can inform their understanding of the problem.
4. **Analyze Insights Using Mental Models:** Encourage experts to apply the selected mental models to analyze different aspects of the problem. Help them identify patterns, relationships, and potential solutions based on their interdisciplinary analysis.
5. **Synthesize Findings with Mental Models:** Synthesize the insights and findings from each discipline using the selected mental models. Look for common themes, connections, or contradictions that emerge across disciplines.
6. **Develop Solutions Integrating Mental Models:** Based on the synthesized findings, develop solutions or recommendations that integrate insights from multiple disciplines and mental models. Consider how different models can complement each other to address the problem comprehensively.
7. **Communicate and Collaborate with Stakeholders:** Communicate the multidisciplinary findings and solutions effectively to stakeholders, policymakers, or relevant audiences. Emphasize the role of mental models in enhancing interdisciplinary understanding and problem-solving.

Interdisciplinarity with Mental Models:

1. **Define the Research Question or Problem:** Articulate a research question or problem that requires an interdisciplinary approach and is amenable to mental model analysis.
2. **Identify Relevant Disciplines and Mental Models:** Identify disciplines and associated mental models that can provide valuable insights into different aspects of the research question. Choose models that offer complementary perspectives and methodologies.
3. **Establish a Collaborative Team:** Form a collaborative team of researchers or experts from the identified disciplines, ensuring diversity in expertise and familiarity with mental models. Facilitate team discussions to introduce and integrate mental models into the research process.
4. **Integrate Mental Models into Data Collection and Analysis:** Incorporate mental models into the data collection and analysis process, using them as frameworks for interpreting and synthesizing interdisciplinary data. Encourage team members to apply their respective mental models to generate insights.
5. **Develop an Integrative Framework with Mental Models:** Develop an integrative framework that incorporates insights from different disciplines and mental models. Use the framework to guide the analysis and interpretation of research findings.
6. **Interpret Findings Using Mental Models:** Interpret the research findings within the context of the integrative framework and associated mental models. Explore how different models illuminate different aspects of the research question and contribute to a comprehensive understanding.
7. **Communicate Results Highlighting Mental Model Integration:** Communicate the interdisciplinary findings and implications to academic audiences, practitioners, or stakeholders, emphasizing the role of mental models in facilitating interdisciplinary collaboration and knowledge integration.

Transdisciplinarity with Mental Models:

1. **Identify a Complex Issue Requiring Transdisciplinary Collaboration:** Select a complex social or environmental issue that transcends disciplinary boundaries and can benefit from a transdisciplinary approach informed by mental models.

2. **Form a Transdisciplinary Team with Mental Model Expertise:** Assemble a transdisciplinary team comprising researchers, practitioners, and stakeholders with expertise in relevant disciplines and mental models. Foster a shared understanding of the issue and the potential contributions of mental models to its analysis.
3. **Define Shared Goals and Objectives Incorporating Mental Models:** Establish shared goals and objectives that reflect the collective vision of the transdisciplinary team, integrating insights from relevant mental models. Use the goals to guide collaborative research and problem-solving efforts.
4. **Engage in Reflexive Dialogue and Knowledge Integration with Mental Models:** Facilitate reflexive dialogue and knowledge integration among team members, incorporating mental models as tools for exploring diverse perspectives, assumptions, and values. Encourage mutual learning and co-production of knowledge.
5. **Co-design and Co-implement Interventions Informed by Mental Models:** Co-design and co-implement interventions or strategies informed by insights from relevant mental models. Involve stakeholders in decision-making and action planning, drawing on interdisciplinary and transdisciplinary expertise.
6. **Monitor and Evaluate Impact Using Mental Models:** Continuously monitor and evaluate the impact of interventions on the complex issue and the broader system, using mental models to guide the assessment of outcomes and feedback mechanisms. Adapt interventions as needed based on insights gained.
7. **Reflect and Adapt the Transdisciplinary Approach with Mental Models:** Reflect on the transdisciplinary process and outcomes, considering the role of mental models in facilitating collaboration and knowledge integration. Adapt the approach and strategies based on feedback and evolving understanding of the issue.

By following these steps and integrating relevant mental models into multidisciplinary, interdisciplinary, and transdisciplinary approaches, researchers and practitioners can enhance their ability to address complex problems and generate holistic solutions that draw on diverse perspectives and insights.

Certainly! Integrating mental models into multidisciplinary, interdisciplinary, and transdisciplinary approaches can enhance problem-solving, decision-

making, and knowledge integration across disciplines. Here are comprehensive steps for each approach:

Multidisciplinary with Mental Models:

1. **Identify the Problem:** Define the problem or topic requiring a multidisciplinary approach, considering its complexity and potential intersections with various disciplines.
2. **Select Relevant Mental Models:** Identify relevant mental models that can provide insights into different aspects of the problem. Choose models from psychology, economics, sociology, biology, etc., based on their applicability.
3. **Engage Experts from Different Disciplines:** Collaborate with experts from relevant disciplines and introduce them to the selected mental models. Facilitate discussions to explore how these models can inform their understanding of the problem.
4. **Analyze Insights Using Mental Models:** Encourage experts to apply the selected mental models to analyze different aspects of the problem. Help them identify patterns, relationships, and potential solutions based on their interdisciplinary analysis.
5. **Synthesize Findings with Mental Models:** Synthesize the insights and findings from each discipline using the selected mental models. Look for common themes, connections, or contradictions that emerge across disciplines.
6. **Develop Solutions Integrating Mental Models:** Based on the synthesized findings, develop solutions or recommendations that integrate insights from multiple disciplines and mental models. Consider how different models can complement each other to address the problem comprehensively.
7. **Communicate and Collaborate with Stakeholders:** Communicate the multidisciplinary findings and solutions effectively to stakeholders, policymakers, or relevant audiences. Emphasize the role of mental models in enhancing interdisciplinary understanding and problem-solving.

Interdisciplinarity with Mental Models:

1. **Define the Research Question or Problem:** Articulate a research question or problem that requires an interdisciplinary approach and is amenable to mental model analysis.
2. **Identify Relevant Disciplines and Mental Models:** Identify disciplines and associated mental models that can provide valuable insights into different aspects of the research question. Choose models that offer complementary perspectives and methodologies.
3. **Establish a Collaborative Team:** Form a collaborative team of researchers or experts from the identified disciplines, ensuring diversity in expertise and familiarity with mental models. Facilitate team discussions to introduce and integrate mental models into the research process.
4. **Integrate Mental Models into Data Collection and Analysis:** Incorporate mental models into the data collection and analysis process, using them as frameworks for interpreting and synthesizing interdisciplinary data. Encourage team members to apply their respective mental models to generate insights.
5. **Develop an Integrative Framework with Mental Models:** Develop an integrative framework that incorporates insights from different disciplines and mental models. Use the framework to guide the analysis and interpretation of research findings.
6. **Interpret Findings Using Mental Models:** Interpret the research findings within the context of the integrative framework and associated mental models. Explore how different models illuminate different aspects of the research question and contribute to a comprehensive understanding.
7. **Communicate Results Highlighting Mental Model Integration:** Communicate the interdisciplinary findings and implications to academic audiences, practitioners, or stakeholders, emphasizing the role of mental models in facilitating interdisciplinary collaboration and knowledge integration.

Transdisciplinarity with Mental Models:

1. **Identify a Complex Issue Requiring Transdisciplinary Collaboration:** Select a complex social or environmental issue that transcends disciplinary boundaries and can benefit from a transdisciplinary approach informed by mental models.
2. **Form a Transdisciplinary Team with Mental Model Expertise:** Assemble a transdisciplinary team comprising researchers, practitioners, and stakeholders with expertise in relevant disciplines and mental models. Foster a shared understanding of the issue and the potential contributions of mental models to its analysis.
3. **Define Shared Goals and Objectives Incorporating Mental Models:** Establish shared goals and objectives that reflect the collective vision of the transdisciplinary team, integrating insights from relevant mental models. Use the goals to guide collaborative research and problem-solving efforts.
4. **Engage in Reflexive Dialogue and Knowledge Integration with Mental Models:** Facilitate reflexive dialogue and knowledge integration among team members, incorporating mental models as tools for exploring diverse perspectives, assumptions, and values. Encourage mutual learning and co-production of knowledge.
5. **Co-design and Co-implement Interventions Informed by Mental Models:** Co-design and co-implement interventions or strategies informed by insights from relevant mental models. Involve stakeholders in decision-making and action planning, drawing on interdisciplinary and transdisciplinary expertise.
6. **Monitor and Evaluate Impact Using Mental Models:** Continuously monitor and evaluate the impact of interventions on the complex issue and the broader system, using mental models to guide the assessment of outcomes and feedback mechanisms. Adapt interventions as needed based on insights gained.
7. **Reflect and Adapt the Transdisciplinary Approach with Mental Models:** Reflect on the transdisciplinary process and outcomes, considering the role of mental models in facilitating collaboration and knowledge integration. Adapt the approach and strategies based on feedback and evolving understanding of the issue.

By following these steps and integrating relevant mental models into multidisciplinary, interdisciplinary, and transdisciplinary approaches, researchers and practitioners can enhance their ability to address complex

problems and generate holistic solutions that draw on diverse perspectives and insights.

Certainly! Let's break down each approach and provide comprehensive steps for thinking in a multidisciplinary, interdisciplinary, and transdisciplinary manner:

Multidisciplinary Thinking:

1. **Identify the Problem or Topic:** Clearly define the problem or topic that requires a multidisciplinary approach. Consider its complexity and the potential contributions of various disciplines.
2. **Identify Relevant Disciplines:** Determine which disciplines are relevant to the problem or topic. Consider fields such as psychology, economics, biology, sociology, etc., that may offer valuable insights.
3. **Understand Core Concepts and Perspectives:** Develop a basic understanding of the core concepts, theories, and methodologies used in each relevant discipline. Consider how they approach the problem from different perspectives.
4. **Analyze Insights from Different Disciplines:** Analyze the insights and perspectives offered by each discipline. Look for commonalities, differences, and potential synergies that can inform a comprehensive understanding of the problem.
5. **Integrate Perspectives and Synthesize Findings:** Integrate the perspectives and findings from different disciplines to develop a holistic understanding of the problem. Synthesize the diverse insights into a cohesive framework or analysis.
6. **Evaluate Implications and Generate Solutions:** Consider the implications of the multidisciplinary analysis and generate potential solutions or approaches to address the problem. Evaluate the feasibility, effectiveness, and ethical considerations of each option.
7. **Communicate Across Disciplines:** Effectively communicate the multidisciplinary findings and proposed solutions to stakeholders, policymakers, or relevant audiences. Use clear and accessible language to bridge disciplinary boundaries and foster understanding.

Interdisciplinary Thinking:

1. **Define the Research Question or Problem:** Clearly articulate a research question or problem that requires an interdisciplinary approach. Ensure that it involves aspects that cannot be adequately addressed within a single discipline.
2. **Identify Relevant Disciplines and Perspectives:** Identify the disciplines and perspectives that are necessary to address the research question comprehensively. Consider fields such as psychology, sociology, economics, biology, etc.
3. **Understand Interconnections and Interdependencies:** Explore how concepts, theories, and methodologies from different disciplines intersect and influence each other in relation to the research question. Identify areas of overlap and potential gaps in understanding.
4. **Facilitate Collaboration and Knowledge Exchange:** Foster collaboration and knowledge exchange among experts from different disciplines. Create opportunities for interdisciplinary dialogue, brainstorming, and problem-solving.
5. **Integrate Disciplinary Insights and Synthesize Findings:** Integrate the insights and findings from different disciplines into a cohesive analysis or framework. Synthesize the diverse perspectives to develop a nuanced understanding of the research question.
6. **Generate Innovative Solutions and Approaches:** Draw on the interdisciplinary analysis to generate innovative solutions or approaches to address the research question. Consider how different perspectives can complement each other and lead to novel insights.
7. **Communicate Across Disciplines and Stakeholders:** Communicate the interdisciplinary findings and proposed solutions effectively to academic audiences, practitioners, policymakers, or other stakeholders. Use interdisciplinary language and approaches to foster collaboration and engagement.

Transdisciplinary Thinking:

1. **Identify a Complex Issue Requiring Transdisciplinary Collaboration:** Select a complex social, environmental, or technological issue that transcends disciplinary boundaries and requires collaboration between academia, practitioners, and stakeholders.
2. **Engage Stakeholders and Define Shared Goals:** Engage stakeholders from diverse backgrounds in defining shared goals and objectives for addressing the complex issue. Foster a collaborative and inclusive approach to problem-solving.
3. **Facilitate Reflexive Dialogue and Knowledge Integration:** Facilitate reflexive dialogue and knowledge integration among stakeholders, researchers, and practitioners. Encourage open exchange of ideas, perspectives, and experiences to build mutual understanding and trust.
4. **Co-create and Co-implement Interventions:** Co-create and co-implement interventions or strategies that address the root causes of the complex issue. Involve stakeholders in all stages of the process, from problem definition to evaluation and adaptation.
5. **Monitor and Evaluate Impact:** Continuously monitor and evaluate the impact of interventions on the complex issue and the broader system. Use participatory and adaptive evaluation approaches to engage stakeholders in ongoing learning and improvement.
6. **Reflect and Adapt the Transdisciplinary Approach:** Reflect on the transdisciplinary process and outcomes to identify lessons learned and areas for improvement. Adapt the approach and strategies based on feedback and evolving understanding of the issue and context.
7. **Share Insights and Lessons Learned:** Share insights, best practices, and lessons learned from the transdisciplinary process with other stakeholders, organizations, and communities. Contribute to collective learning and capacity-building efforts to address similar issues in different contexts.

By following these comprehensive steps and embracing multidisciplinary, interdisciplinary, and transdisciplinary thinking, individuals and teams can enhance their ability to tackle complex problems and generate innovative solutions that draw on diverse perspectives, expertise, and approaches.

Certainly! Let's break down each approach and provide comprehensive steps for applying logic in multidisciplinary, interdisciplinarity, and transdisciplinarity:

Multidisciplinary Logic:

1. **Identify the Problem or Topic:** Clearly define the problem or topic that requires a multidisciplinary approach. Consider its complexity and the potential intersections with various disciplines.
2. **Identify Relevant Disciplines:** Determine which disciplines are relevant to the problem or topic. Consider fields such as psychology, economics, biology, sociology, etc., that may offer valuable insights.
3. **Understand Core Concepts and Perspectives:** Develop a basic understanding of the core concepts, theories, and methodologies used in each relevant discipline. Consider how they approach the problem from different perspectives.
4. **Analyze Insights from Different Disciplines:** Apply logical reasoning to analyze the insights and perspectives offered by each discipline. Evaluate the validity and reliability of the information and identify any potential biases or assumptions.
5. **Integrate Perspectives and Synthesize Findings:** Use logical reasoning to integrate the perspectives and findings from different disciplines. Look for commonalities, differences, and potential synergies that can inform a comprehensive understanding of the problem.
6. **Evaluate Implications and Generate Solutions:** Apply logical reasoning to evaluate the implications of the multidisciplinary analysis and generate potential solutions or approaches to address the problem. Consider the feasibility, effectiveness, and ethical considerations of each option.
7. **Communicate Across Disciplines:** Effectively communicate the multidisciplinary findings and proposed solutions to stakeholders, policymakers, or relevant audiences. Use clear and logical arguments to bridge disciplinary boundaries and foster understanding.

Interdisciplinarity Logic:

1. **Define the Research Question or Problem:** Clearly articulate a research question or problem that requires an interdisciplinary approach. Ensure that it involves aspects that cannot be adequately addressed within a single discipline.
2. **Identify Relevant Disciplines and Perspectives:** Identify the disciplines and perspectives that are necessary to address the research question comprehensively. Consider fields such as psychology, sociology, economics, biology, etc.
3. **Understand Interconnections and Interdependencies:** Apply logical reasoning to explore how concepts, theories, and methodologies from different disciplines intersect and influence each other in relation to the research question. Identify areas of overlap and potential gaps in understanding.
4. **Facilitate Collaboration and Knowledge Exchange:** Use logical reasoning to foster collaboration and knowledge exchange among experts from different disciplines. Create opportunities for interdisciplinary dialogue, brainstorming, and problem-solving.
5. **Integrate Disciplinary Insights and Synthesize Findings:** Apply logical reasoning to integrate the insights and findings from different disciplines into a cohesive analysis or framework. Synthesize the diverse perspectives to develop a nuanced understanding of the research question.
6. **Generate Innovative Solutions and Approaches:** Apply logical reasoning to generate innovative solutions or approaches to address the research question. Consider how different perspectives can complement each other and lead to novel insights.
7. **Communicate Across Disciplines and Stakeholders:** Use logical arguments to communicate the interdisciplinary findings and proposed solutions effectively to academic audiences, practitioners, policymakers, or other stakeholders. Foster interdisciplinary understanding and collaboration.

Transdisciplinarity Logic:

1. **Identify a Complex Issue Requiring Transdisciplinary Collaboration:** Select a complex social, environmental, or technological issue that transcends disciplinary boundaries and requires collaboration between academia, practitioners, and stakeholders.
2. **Engage Stakeholders and Define Shared Goals:** Use logical reasoning to engage stakeholders from diverse backgrounds in defining shared goals and objectives for addressing the complex issue. Foster a collaborative and inclusive approach to problem-solving.
3. **Facilitate Reflexive Dialogue and Knowledge Integration:** Apply logical reasoning to facilitate reflexive dialogue and knowledge integration among stakeholders, researchers, and practitioners. Encourage open exchange of ideas, perspectives, and experiences.
4. **Co-create and Co-implement Interventions:** Use logical reasoning to co-create and co-implement interventions or strategies that address the root causes of the complex issue. Involve stakeholders in all stages of the process, from problem definition to evaluation and adaptation.
5. **Monitor and Evaluate Impact:** Apply logical reasoning to continuously monitor and evaluate the impact of interventions on the complex issue and the broader system. Use participatory and adaptive evaluation approaches to engage stakeholders in ongoing learning and improvement.
6. **Reflect and Adapt the Transdisciplinary Approach:** Use logical reasoning to reflect on the transdisciplinary process and outcomes, identifying lessons learned and areas for improvement. Adapt the approach and strategies based on feedback and evolving understanding of the issue and context.
7. **Share Insights and Lessons Learned:** Use logical arguments to share insights, best practices, and lessons learned from the transdisciplinary process with other stakeholders, organizations, and communities. Contribute to collective learning and capacity-building efforts.

By applying logical reasoning in multidisciplinary, interdisciplinarity, and transdisciplinarity, individuals and teams can enhance their ability to tackle complex problems and generate innovative solutions that draw on diverse perspectives, expertise, and approaches.

Step 77 - Understand How the World Really Works

Understanding how the world really works is a complex and multifaceted endeavor, but here are some key aspects to consider:

1. **Power Dynamics:** Much of the world operates based on power structures, whether they are political, economic, or social. Those who hold power often shape the direction of global events and policies.
2. **Economics:** Money and resources play a significant role in shaping the world. Economic systems, such as capitalism and socialism, influence how wealth is distributed and how societies function.
3. **Politics:** Governments, international organizations, and diplomatic relations all impact global affairs. Understanding geopolitics involves analyzing the interactions between different countries and regions.
4. **Technology:** Advancements in technology continually reshape the world, affecting everything from communication and commerce to warfare and healthcare.
5. **Culture:** Cultural beliefs, norms, and values influence individual and collective behavior. Cultural factors shape how societies operate and interact with one another.
6. **Environment:** The natural world has a profound impact on human societies, and human activities, in turn, affect the environment. Climate change, resource depletion, and environmental degradation are significant global challenges.
7. **History:** The past influences the present, and understanding historical events and patterns can provide insights into current affairs and future trends.
8. **Globalization:** The interconnectedness of economies, cultures, and societies across the world has led to increased interdependence and complex interactions.
9. **Human Behavior:** Psychology and sociology offer valuable insights into individual and group behavior, helping to understand why people act in certain ways and how societies function.
10. **Conflict and Cooperation:** Conflicts over resources, ideology, and power are prevalent in global affairs, but cooperation and diplomacy also play crucial roles in addressing common challenges.

These factors interact in intricate ways, shaping the world we live in and influencing the course of events on local, national, and global scales. Understanding how the world really works requires considering these factors holistically and recognizing their interconnectedness.

Certainly! Here's a step-by-step guide on how to understand how the world really works and how to apply mental models to navigate its complexity:

1. **Study Various Disciplines:** Begin by studying different disciplines such as economics, political science, sociology, psychology, history, and environmental science. Each discipline offers unique perspectives and insights into different aspects of the world.
2. **Develop Critical Thinking Skills:** Cultivate critical thinking skills to evaluate information critically, question assumptions, and analyze complex problems. Learn to distinguish between reliable sources and misinformation.
3. **Learn about Mental Models:** Mental models are frameworks for understanding the world. Study different mental models such as Occam's Razor, Bayesian Thinking, Second-Order Thinking, and Inversion. Each model provides a lens through which to view and interpret information.
4. **Apply Mental Models:** Practice applying mental models to real-world situations. When faced with a problem or decision, consider which mental model might be most applicable and use it to guide your thinking.
5. **Seek Diverse Perspectives:** Engage with diverse perspectives and viewpoints to broaden your understanding of the world. Listen to people with different backgrounds, experiences, and beliefs to gain new insights and challenge your own assumptions.
6. **Stay Informed:** Stay informed about current events and global trends. Follow reputable news sources and seek out in-depth analysis to understand the context behind the headlines.
7. **Connect the Dots:** Look for connections between different events, trends, and phenomena. Consider how seemingly unrelated factors might be interconnected and influencing one another.
8. **Think Systematically:** Adopt a systemic approach to understanding the world. Recognize that systems are composed of interconnected parts, and changes in one part can have ripple effects throughout the system.
9. **Practice Scenario Planning:** Anticipate different possible outcomes and scenarios based on your understanding of the world. Consider how different factors might interact to shape future events and prepare accordingly.
10. **Reflect and Iterate:** Continuously reflect on your understanding of the world and refine your mental models based on new information and experiences. Be open to updating your beliefs and adapting your thinking as you learn more.

By following these steps and applying mental models to your understanding of the world, you can develop a more nuanced and informed perspective on global affairs and better navigate its complexity.

Certainly! Here's a step-by-step guide on how to apply mental models to navigate the complexities of the world and integrate your understanding of how the world really works:

1. **Understand Mental Models:** Begin by familiarizing yourself with various mental models that offer frameworks for understanding and analyzing complex situations. Some common mental models include Occam's Razor, Pareto Principle, Second-Order Thinking, and Inversion.
2. **Identify Relevant Mental Models:** Assess the situation or problem you're facing and determine which mental models might be most applicable. Consider factors such as the nature of the problem, the stakeholders involved, and the desired outcomes.
3. **Analyze the Situation:** Break down the situation into its component parts and gather relevant information. Consider the various factors at play, including economic, political, social, and environmental aspects.
4. **Apply Mental Models:** Choose one or more mental models that seem relevant to the situation and apply them to gain insights. For example, if you're analyzing a decision, you might use Second-Order Thinking to consider the potential consequences beyond the immediate effects.
5. **Consider Interconnections:** Recognize that the world is interconnected, and different factors often influence one another. Use mental models to explore the interconnections between various aspects of the situation and identify potential leverage points or areas of intervention.
6. **Evaluate Options:** Use the insights gained from applying mental models to evaluate different options or courses of action. Consider the potential risks, benefits, trade-offs, and unintended consequences associated with each option.
7. **Make Informed Decisions:** Use your analysis and evaluation to make informed decisions that are aligned with your goals and values. Consider how your decisions may impact different stakeholders and anticipate potential reactions or responses.
8. **Monitor and Adapt:** Continuously monitor the situation and be prepared to adapt your approach as new information becomes available. Use mental models to reassess the situation and identify opportunities for improvement or course correction.
9. **Seek Feedback and Learning:** Solicit feedback from others and be open to learning from both successes and failures. Reflect on your experiences and consider how you can refine your application of mental models in future situations.
10. **Integrate Learning with Understanding of the World:** Connect your application of mental models with your broader understanding of how the world really works. Recognize the contextual factors that shape the situation and consider how larger social, economic, political, and environmental dynamics may influence outcomes.
11. **Share Insights and Collaborate:** Share your insights and perspectives with others, and collaborate with individuals who have complementary skills and knowledge. By combining diverse perspectives and expertise, you can generate more robust analyses and solutions. By following these steps, you can effectively apply mental models to navigate the complexities of the world and integrate your understanding of how the world really works into your decision-making and problem-solving processes.

0A. All Models Are Wrong

How is your journey towards understanding Farnam Street's latticework of mental models going? Is it proving useful? Changing your view of the world? If the answer is that it's going well that's good. There's just one tiny hitch.

All models are wrong.

Yep. It's the truth. However, there is another part to that statement:

All models are wrong; some are useful.

Those words come from the British statistician, George Box. In a groundbreaking 1976 paper, Box revealed the fallacy of our desire to categorize and organize the world. We create models (a term with many applications), once to confuse them for reality.

Box also stated:

Remember that all models are wrong; the practical question is how wrong do they have to be to not be useful.

What Exactly Is A Model?

First, we should understand precisely what a model is.

The dictionary definition states a model is 'a representation, generally in miniature, to show the construction or appearance of something' or 'a simplified description, especially a mathematical one, of a system or process, to assist calculations and predictions.'

For our purposes here, we are better served by the second definition. A model is a simplification which fosters understanding.

Think of an architectural model. These are typically a small scale model of a building, made before it's built. Its purpose is to show what the building will look like and to help people working on the project to develop a clear picture of the overall feel. In the iconic scene from Zoolander, Derek (played by Ben Stiller) looks at the architectural model of his proposed 'school for kids who can't read good' and shouts "What is this? A center for ants??"

That scene illustrates the wrong way to understand models: Too literally.

Why We Use Models- And Why They Work

At Farnam Street, we believe in using models for the purpose of building a massive, but finite amount of fundamental, invariant knowledge about how the world really works.

Applying this knowledge is the key to making good decisions and avoiding stupidity.

"Scientists generally agree that no theory is 100 percent correct. Thus, the real test of knowledge is not truth, but utility. Science gives us power. The more useful that power, the better the science."

— Yuval Noah Harari

Time-tested models allow us to understand how things work in the real world. And understanding how things work prepares us to make better decisions without expending too much mental energy in the process.

Instead of relying on fickle and specialized facts, we can learn versatile concepts.

The mental models we cover are intended to be widely applicable.

It's crucial for us to understand as many mental models as possible. As the adage goes, a little knowledge can be dangerous and creates more problems than total ignorance. No single model is universally applicable – we find exceptions for nearly everything. Even hardcore physics has not been totally solved.

"The basic trouble, you see, is that people think that "right" and "wrong" are absolute; that everything that isn't perfectly and completely right is totally and equally wrong."

— Isaac Asimov

Take a look at almost any comment section on the internet and you are guaranteed to find at least one pedant raging about a minor perceived inaccuracy, throwing out the good with

the bad. While ignorance and misinformation are certainly not laudable, neither is an obsession with perfection.

Like heuristics, models work as a consequence of the fact they are usually helpful in most situations, not because they are always helpful in a small number of situations.

Models can assist us in making predictions and forecasting the future. Forecasts are never guaranteed, yet they provide us with a degree of preparedness and comprehension of the future. For example, a weather forecast which claims it will rain today may get that wrong. Still, it's correct often enough to enable us to plan appropriately and bring an umbrella.

Mental Models and Minimum Viable Products

Think of mental models as minimum viable products.

Sure, all of them can be improved. But the only way that can happen is if we try them out, educate ourselves and collectively refine them.

We can apply one of our mental models, Occam's razor, to this. Occam's razor states that the simplest solution is usually correct. In the same way, our simplest mental models tend to be the most useful. This is because there is minimal room for errors and misapplication. *"The world doesn't have the luxury of waiting for complete answers before it takes action."*

— Daniel Gilbert

Your kitchen knives are not as sharp as they could be. Does that matter as long as they still cut vegetables? Your bed is not as comfortable as it could be. Does that matter if you can still get a good night's sleep in it? Your internet is not as fast as it could be. Does that matter as long as you can load this article? Arguably not. Our world runs on the functional, not the perfect. This is what a mental model is – a functional tool. A tool which maybe could be a bit sharper or easier to use, but still does the job.

The statistician David Hand made the following statement in 2014;

In general, when building statistical models, we must not forget that the aim is to understand something about the real world. Or predict, choose an action, make a decision, summarize evidence, and so on, but always about the real world, not an abstract mathematical world: our models are not the reality.

For example, in 1960, Georg Rasch said the following:

When you construct a model you leave out all the details which you, with the knowledge at your disposal, consider inessential.... Models should not be true, but it is important that they are applicable, and whether they are applicable for any given purpose must, of course, be investigated. This also means that a model is never accepted finally, only on trial.

Imagine a world where physics like precision is prized over usefulness.

We would lack medical care because a medicine or procedure can never be perfect. In a world like this, we would possess little scientific knowledge, because research can never be 100% accurate. We would have no art because a work can never be completed. We would have no technology because there are always little flaws which can be ironed out.

"A model is a simplification or approximation of reality and hence will not reflect all of reality ... While a model can never be "truth," a model might be ranked from very useful, to useful, to somewhat useful to, finally, essentially useless."

— Ken Burnham and David Anderson

In short, we would have nothing. Everything around us is imperfect and uncertain. Some things are more imperfect than others, but issues are always there. Over time, incremental improvements happen through unending experimentation and research.

The Map is Not the Territory

As we know, the map is not the territory. A map can be seen as a symbol or index of a place, not an icon.

When we look at a map of Paris, we know it is a representation of the actual city. There are bound to be flaws; streets which have been renamed, demolished buildings, perhaps a new Metro line. Even so, the map will help us find our way. It is far more useful to have a map showing the way from Notre Dame to Gare du Nord (a tool) than to know how many meters they are apart (a piece of trivia.)

Someone who has spent a lot of time studying a map will be able to use it with greater ease, just like a mental model. Someone who lives in Paris will find the map easier to understand than a tourist, just as someone who uses a mental model in their day to day life will apply it better than a novice. As long as there are no major errors, we can consider the map useful, even if it is by no means a reflection of reality. Gregory Bateson writes in Steps to an Ecology of Mind that the purpose of a map is not to be true, but to have a structure which represents truth within the current context.

“A map is not the territory it represents, but, if correct, it has a similar structure to the territory, which accounts for its usefulness.”

— Alfred Korzybski

Physical maps generally become more accurate as time passes. Not long ago, they often included countries which didn't exist, omitted some which did, portrayed the world as flat or fudged distances. Nowadays, our maps have come a long way.

The same goes for mental models – they are always evolving, being revised – never really achieving perfection. Certainly, over time, the best models are revised only slightly, but we must never consider our knowledge “set”.

Another factor to consider in using models is to take into account what they're used for. Many mental models (e.g. entropy, critical mass and activation energy) are based upon scientific and mathematical concepts. A person who works in those areas will obviously need a deeper understanding of it than someone who want to learn to think better when making investment decisions. They will need a different map and a more detailed one showing elements which the rest of us have no need for.

“A model which took account of all the variation of reality would be of no more use than a map at the scale of one to one.”

— Joan Robinson

In his essay *Partial Enchantments of the Quixote*, Jorge Luis Borges provides an even more interesting analysis of the confusion between models and reality:

Let us imagine that a portion of the soil of England has been leveled off perfectly and that on it a cartographer traces a map of England. The job is perfect; there is no detail of the soil of England, no matter how minute that is not registered on the map; everything has there its correspondence. This map, in such a case, should contain a map of the map, which should contain a map of the map of the map, and so on to infinity. Why does it disturb us that the map be included in the map and the thousand and one nights in the book of the Thousand and One Nights? Why does it disturb us that Don Quixote be a reader of the Quixote and Hamlet a spectator of Hamlet? I believe I have found the reason: these inversions suggest that if the characters of a fictional work can be readers or spectators, we, its readers or spectators, can be fictions.

How Do We Know If A Model Is Useful?

This is a tricky question to answer. When looking at any model, it is helpful to ask some of the following questions:

- How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile.

Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.

- Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
- Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
- How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
- Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
- Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to require extensive knowledge of a particular topic, and have minimal real-world application.

When using any mental model, we must avoid becoming too rigid. There are exceptions to all of them, and situations in which they are not applicable.

Think of the latticework as a toolkit. That's why it pays to do the work up front to put so many of them in your toolbox at a deep, deep level. If you only have one or two, you're likely to attempt to use them in places that don't make sense. If you've absorbed them only lightly, you will not be able to use them when the time is at hand.

If on the other hand, you have a toolbox full of them and they're sunk in deep, you're more likely to pull out the best ones for the job exactly when they are needed.

Too many people are caught up wasting time on physics-like precision in areas of practical life that do not have such precision available. A better approach is to ask "Is it useful?" and, if yes, "To what extent?"

Mental models are a way of thinking about the world that prepares us to make good decisions in the first place.

0B. Mental Models (Use mental models).

1. Three Ways You're Wrong in a Disagreement (Even if You're Right)

Kathryn Schulz, the illuminating author of Being Wrong: Adventures in the Margin of Error, gave an excellent talk at TED talk on being wrong.

There is a moment in her talk when she summarizes what we do when someone disagrees with us that is worth pondering.

... The first thing we usually do when someone disagrees with us is that we just assume they are ignorant. You know, they don't have access to the same information we do and when we generously share that information with them, they are going to see the light and come on over to our team.

When that doesn't work. When it turns out those people have all the same information and they still don't agree with us we move onto a second assumption. They're idiots. They have all the right pieces of the puzzle and they are too moronic to put them together.

And when that doesn't work. When it turns out that people have all the same facts that we do and they are pretty smart we move onto a third assumption. They know the truth and they are deliberately distorting it for their own malevolent purposes.

So this is a catastrophe: our attachment to our own rightness. It prevents us from preventing mistakes when we need to and causes us to treat each other terribly.

And this is what it's like to come face to face with someone that disagrees with us.

That point isn't really whether we're right and they're wrong or they're right and we're wrong — often neither of us are perfectly correct. The point is how our ego subconsciously works to protect itself from anyone and anything that doesn't entirely agree with us.

Rather than open ourselves up to how the world works, we instead put on blinders that tell us we don't need to consider the possibility that the only thing wrong is that we think the other person is wrong and not ourselves.

2. This is a World of Incentives

I thought Warren Buffett said a lot of interesting things in his recent interview with Charlie Rose.

Here are some of the bits that stood out for me.

Fairness:

BUFFETT: ...I also think fairness is important and I think getting rid of promises that you can't keep is important. I don't think we should cut spending dramatically now. I don't think that what I'm talking about on taxes solves the — the deficit gap at all. But I think fairness is important. I think having a sensible long-term plan is important to explain and I think having it be believable is terribly important because people don't believe these out year things generally with Congress. They see too much of what's happened.

The deficit as stimulus

BUFFETT: The deficit is our stimulus. You can — you can say a bridge someplace is part of that act, you can say cutting taxes is part of it as was the case in our stimulus act. But the stimulus is the government pouring more money out than it's taking in. And we have a — a stimulus going on that's 10 percent of GDP which we haven't seen since World War II. So we have a huge stimulus going on. Nobody wants to call it a stimulus because that's gotten to be a dirty word. But we have a big stimulus. So we do — in my view, whether we have a 10 percent of GDP deficit —

ROSE: Right.

BUFFETT: — which is a huge stimulus or a 12 percent or eight percent it doesn't make much difference. I — I think that we pushed monetary policy to a level, we've pushed fiscal policy to the limit but fortunately the most important thing in terms of this country ever coming out of recessions has been the natural workings of capitalism and I think you've seen that for the last couple of years.

Following through

BUFFETT: What our leaders were saying to us then, the key players are saying we'll do whatever it takes. And I believed it. I knew they had the power to do whatever it took and I believed they would do it.

Now, the problem about government now is that if they come out and get on the Sunday talks shows and say "I'll do whatever it takes", you know, people don't believe them. And I mean, they — they — they've got to see action and — and here they see something like the raising the deficit limit used as a hostage for something of vital importance to the United States. And if you — you can use it as a hostage in terms of spending, you can use it as a hostage on funding on education or anything else. I mean, it isn't limited about it; if you've got something that comes up like it.

Incentives

BUFFETT: But I just use it to illustrate that this is a world of incentives and we work on incentives in every way. If we work on education, in business, every other place. And what I try to think of the incentives to get somebody who comes up for re-election in a year to do something where the policy cycle goes out five years or ten years, how do you do it when the policy cycle exceeds the electoral cycle? You've got to make sure the electoral cycle is in the equation.

3. Alignment: The Key to Success Nobody Ever Taught You

I spend a lot of time thinking about this simple idea: The person who aligns themselves with the general principles of the world goes further and faster than the person who doesn't.

What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson.

— Joseph Tussman

The way to align yourself with the world is to take simple ideas seriously.

Consider compounding.

We know that spending less than we make, investing the difference in index funds, and waiting for a long time creates financial independence. Yet how many people follow this principle? Not many. Most of us know what works but fail to align ourselves with it.

Compounding applies to relationships too. Not just with your partner, but with your colleagues, friends, and even your customers. For relationships to compound, they must be win-win. But how many people take a consistent win-win approach? Not many. Again, we know what works, but fail to align ourselves with it.

Outcome over Ego

Here's the trick to seeing things differently: put your energy into *being* right, not *feeling* right. While that sounds simple, it's far from easy.

If you want to be right, you have to change your mind. When the evidence indicates the approach isn't working, change the approach. This is easy with something like math, where the answers are black and white, but harder with more subjective things.

Often the hardest things to change our minds about are the things that require us to understand that just because we can't see the results immediately doesn't mean they are not moving us closer or further from the outcome we want. For instance, eating a full pizza once won't make you unhealthy, but repeating that choice daily for years certainly will.

Feeling right, on the other hand, often requires you to believe you are an exception. You know the path to financial independence, but that takes too long. It's boring. Instead, you'd rather try the latest incarnation of a get-rich-quicker scheme that promises the outcome sooner. When it inevitably fails to produce the desired results, rather than tell yourself you made a mistake you chalk it up to the world not working as it should. It's as if that little voice in your head says, "You're not wrong; the world is."

Most of us would rather bargain with how the world works than accept how it does work, cooperate with it, and move forward. This happens in a lot of areas of life. Consider the general concept of health.

A lot of people think they don't have to take care of their health. They get too little sleep. They drink too much. They eat incredible amounts of processed food. They get little to no exercise. While they know health is important, at some level they think they are the exception. Acceptance is knowing you must care for your health because it is the foundation for everything else. Without health, everything else multiplies by zero.

We are tempted to believe we're the exception because it's the easy path.

Aligning with the world often requires you to pre-pay now for a result later. A little bit of pain today for gain tomorrow. And we don't like the sounds of that.

However, if you can align yourself with the world despite what those around you do, you'll quickly discover that it tends to do most of the work for you. It just won't take the first step for you. You have to take that one for yourself.

4. Born, and Evolved, to Run

Daniel Lieberman, author of *The Evolution of the Human Head*, sat down with the NYT for an interesting conversation.

Some years ago, I was doing an experiment where I put pigs on treadmills. The goal was to learn how running stressed the bones in the head. One day, a colleague, Dennis Bramble, walked into the lab, watched what was going on, and declared, "You know, that pig can't hold its head still!"

This was my "eureka!" moment. I'd observed pigs on treadmills for hundreds of hours and had never thought about this. So Dennis and I started talking about how, when these pigs ran, their heads bobbed every which way and how running humans are really adept at stabilizing their heads. We realized that there were special features in the human neck that enable us to keep our heads still. That gives us an evolutionary advantage because it helps us avoid falls and injuries. And this seemed like evidence of natural selection in our ability to run, an important factor in how we became hunters rather than just foragers and got access to richer foods, which fueled the evolution of our big brains.

So I got interested in how we developed these stable heads. I'm a runner myself. It's always interesting to study one's passion. By 2004, we'd found enough evidence to publish a paper in Nature where we declared, "Humans were born to run." We cited the many dozens of adaptations in the human body that had made us into superlative endurance runners, even compared to dogs and horses.

Before bows and arrows and before horses were tamed, we did "persistence hunting" where we ran kudu, wildebeest and zebra into exhaustion. These animals can't pant when they gallop. They overheat. People would find a big animal and chase it till it collapsed. You need no technology to do this, just the ability to run long distances, which all of us have.

You can see proof of this capability every November when 45,000 people run for many hours through the streets of New York.

5. David Quammen on Why Big Populations Survive and Small Ones Go Extinct

*"Big populations don't go extinct. Small populations do.
It's not a surprising finding but it is a significant one."*

Why do small populations go extinct?

While the answer is simple to outline the scientific details are more nuanced. For now, let's stick to the outline version.

"Small populations go extinct because (1) all populations fluctuate in size from time to time, under the influence of two kinds of factors, which ecologists refer to as deterministic and stochastic; and (2) small populations, unlike big ones, stand a good chance of fluctuation to zero, since zero is not far away."

Deterministic factors are those involving straightforward cause-and-effect relations that to some extent can be predicted and controlled: hunting, trapping, destroying habitat, introducing new animals that compete with or prey on existing ones, etc.

Stochastic factors "operate in a realm beyond human prediction and control, either because they are truly random or because they are linked to geophysical or biological causes so obscurely complex that they seem random." We're talking things like weather patterns, epidemic disease, infestation of parasites, forest fires, etc. Each might cause a downward fluctuation in the population of some species.

In Song of the Dodo, David Quammen gives the following illuminating example.

Think of two species that live on the same tiny island. One is a mouse. Total population, ten thousand. The other is an owl. Total population, eighty. The owl is a fierce and proficient mouse eater. The mouse is timorous, fragile, easily victimized. But the mouse population as a collective entity enjoys the security of numbers.

Say that a three-year drought hits the island of owls and mice, followed by a lightning-set fire, accidental events that are hurtful to both species. The mouse population drops to five thousand, the owl population to forty. At the height of the next breeding season a typhoon strikes, raking the treetops and killing an entire generation of unfledged owls. Then a year passes peacefully, during which the owl and the mouse populations both remain steady, with attrition from old age and individual mishaps roughly offset by new births. Next, the mouse suffers an epidemic disease, cutting its population to a thousand, fewer than at any other time within decades. This extreme slump even affects the owl, which begins starving for lack of prey.

Weakened by hunger, the owl suffers its own epidemic, from a murderous virus. Only fourteen birds survive. Just six of those fourteen owls are female, and three of the six are too old to breed. Then a young female owl chokes to death on a mouse. That leaves two fertile females. One of them loses her next clutch of eggs to a snake. The other nests successfully and manages to fledge four young, all four of which happen to be male. The owl population is now depressed to a point of acute vulnerability. Two breeding females, a few older females, a dozen males. Collectively they possess insufficient genetic diversity for adjusting to further troubles, and there is a high chance of inbreeding between mothers and sons. The inbreeding, when it occurs, tends to yield some genetic defects. Meanwhile the mouse population is also depressed far below its original number.

Ten years pass, with the owl population becoming progressively less healthy because of inbreeding. A few further females are hatched, precious additions to the gender balance, though some of them turn out to be congenitally infertile. During that same stretch of time the mouse population rebounds vigorously. Good weather, plenty of food, no epidemics, genetically it's fine—and so the mouse quickly returns to its former abundance.

Then another wildfire scorches the island, killing four adult owls, and, oh, six thousand mice. The four dead owls were all breeding-age females, crucial to the beleaguered population. The six thousand mice were demographically less crucial. Among the owls there now remains only one female who is young and fertile. She develops ovarian cancer,

a problem to which she is susceptible because of the history of inbreeding among her ancestors. She dies without issue. Very bad news for the owl species. Let's give the mouse another plague of woe, just to be fair: a respiratory infection, contagious and lethal, causes eight hundred fatalities. None of this is implausible. These things happen. The owl population—reduced to a dozen mopey males, several dowagers, no fertile females—is doomed to extinction. When the males and the dowagers die off, one by one, leaving not offspring, that's that. The mouse population fluctuates upward in response to the extinction of the owls, a rude signal that life is easier in the absence of predation. Twelve thousand mice. Fifteen thousand. Twenty thousand. But while its numbers are so high it will probably overexploit its own resources and eventually decline again as a consequence of famine. Then rise again. Then decline again. Then ...

The mouse population is a yo-yo on a long string. Despite all the accidental disasters, despite all the ups and downs, the mouse doesn't go extinct because the mouse is not rare. The owl goes extinct. Why? Because life is a gauntlet of uncertainties and the owl's population size, in the best of times, was too small to buffer it against the worst of times.

6. Several Uncomfortable Realities

Something to ponder.

A sobering excerpt from Vaclav Smil's Global Catastrophes and Trends: The Next Fifty Years:

The first is that even the most assiduous deployment of the best available preventive measures (smart policing, clever informants, globe-spanning, electronic intelligence, willingness to undertake necessary military action) will not be able to thwart all planned attacks.

The second reality is that the most dangerous form of terrorist attacks cannot be deterred because the political and ideological motivations for terrorist attacks that characterized Rapoport's (2001) first three waves of terror have blended with religious zealotry and become one with the Muslim concept of martyrdom, providing the perpetrators with an irresistible reward: instant access to paradise. Murder by suicide has deep roots in Muslim history ...

The third sobering consideration is that neither personal instability nor an individuals hopelessness or overt personal defects, factors that come immediately to mind as the most likely drivers, are dependable predictors of candidates for suicidal martyrdom. Nor are such indicators as poverty, level of education, or religious devotion. Institutional manipulation of emotional commitment seems to be a key factor, and one not easily eliminated. Other obvious contributions are rapidly rising youth populations in countries governed by dictatorial regimes with limited economic opportunities, and the disenchantment of second-generation Muslim immigrants with their host societies. But none of these factors can offer any selective guidance to identify the most susceptible individuals and to prevent their murderous suicides.

The fourth consideration is that our understandable fixation on suicidal missions may be misplaced. A dirty bomb containing enough radioactive waste to contaminate several downtown blocks of a major city and cause mass panic (as anything invisible and nuclear is bound to do) can be positioned in a place calculated to have a maximum impact and then remotely detonated. And while Hizbullah's more than 30 days of rocket attacks on Israel in the summer of 2006 were not particularly deadly, they paralyzed a large part of the country and demonstrated how more conventional weapons could be used in the service of terrorism.

7. Kantian Fairness Tendency: The World Isn't Fair

The Kantian Fairness Tendency refers to the pursuit of perfect fairness which causes a lot of terrible problems. Stop expecting the world to be fair and adjust your behavior accordingly.

To learn about this mental model we turn to Charlie Munger, who mentioned it twice. First in this UCCB talk entitled Academic Economics — Strengths and Weaknesses, after Considering Interdisciplinary Needs where he said:

It is not always recognized that, to function best, morality should sometimes appear unfair, like most worldly outcomes. The craving for perfect fairness causes a lot of terrible problems in system function. Some systems should be made deliberately unfair to individuals because they'll be fairer on average for all of us. I frequently cite the example of having your career over, in the Navy, if your ship goes aground, even if it wasn't your fault. I say the lack of justice for the one guy that wasn't at fault is way more than made up by a greater justice for everybody when every captain of a ship always sweats blood to make sure the ship doesn't go aground. Tolerating a little unfairness to some to get a greater fairness for all is a model I recommend to all of you. But again, I wouldn't put it in your assigned college work if you want to be graded well, particularly in a modern law school wherein there is usually an over-love of fairness-seeking process.

The second time was in his essay entitled: The Psychology of Human Misjudgment: Kant was famous for his “categorical imperative,” a sort of a “golden rule” that required humans to follow those behavior patterns that, if followed by all others, would make the surrounding human system work best for everybody. And it is not too much to say that modern acculturated man displays, and expects from others, a lot of fairness as thus defined by Kant.

In a small community having a one-way bridge or tunnel for autos, it is the norm in the United States to see a lot of reciprocal courtesy, despite the absence of signs or signals. And many freeway drivers, including myself, will often let other drivers come in front of them, in lane changes or the like, because that is the courtesy they desire when roles are reversed. Moreover, there is, in modern human culture, a lot of courteous lining up by strangers so that all are served on a “firstcome-first-served” basis.

Also, strangers often voluntarily share equally in unexpected, unearned good and bad fortune. And, as an obverse consequence of such “fair-sharing” conduct, much reactive hostility occurs when fairsharing is expected yet not provided. It is interesting how the world's slavery was pretty well abolished during the last three centuries after being tolerated for a great many previous centuries during which it coexisted with the world's major religions. My guess is that Kantian Fairness Tendency was a major contributor to this result.

* * *

Professor Sanjay Bakshi makes a connection between the Kantian Fairness Tendency and the “law of the higher good” in reference to Machiavelli's famous book The Prince.

Bakshi said this to his students:

Machiavelli's “The Prince” is a great book and should be made compulsory reading for all MBA students.

To many people, The Prince is an evil book. But Joseph L. Badaracco, who teaches a hugely popular course titled “The Moral Leader” at the Harvard Business School uses this book to teach ethics. And he teaches ethics by telling students to follow Machiavelli's advice in The Prince.

In an interview, Badaracco has said that four different takes on The Prince usually emerge in classroom discussions of The Prince at HBS:

Version 1 : “This book is a mess. It was written by a guy who hoped to get to the center of things, was there briefly, offended some of the wrong Medicis, was exiled, was tortured,

and wanted to get back in.” It’s “a scholar’s dream because you can find anything you want in it and play intellectual games. But just put it aside.”

Version 2 : “Now wait a minute. There’s some good common sense in there. Machiavelli is basically saying that if you want to make an omelet you have to break some eggs... To do some right things, you may have to not do some other right things.”

Version 3 : Other students believe the book is still around because it’s so evil. Why is it evil? “If you look closely at *The Prince*,” he said, “it’s quite interesting what isn’t in the book. Nothing about religion. Nothing about the Church. Nothing about God. There’s nothing about spirituality. Almost nothing about the law. Almost nothing about traditions. You’re out there on your own doing what works for you in terms of naked ambition.”

Version 4 : “A fourth Prince that other students uncover is the most interesting one, in Badaracco’s mind. Students find that the book reveals a kind of worldview, he says, and it’s not an evil worldview. This version goes: “If you’re going to make progress in the world you’ve got to have a clear sense, a realistic sense, an unsentimental sense, of how things really work: the mixed motives that compel some people and the high motives that compel some others. And the low motives that unfortunately captivate other people.” Students who claim the fourth Prince, Badaracco said, believe that if they’re going to make a difference, it’s got to be in this world, “and not in some ideal world that you would really like to live in.”

One of my favourite mental models comes from *The Prince*. I call this model, the “law of the higher good”. Before I read *The Prince*, I read an excellent book called, “*The Contrarian Guide to Leadership*” by Steven Sample. In this book, which was recommended by Mr. Munger, Sample’s thoughts on the law of the higher good from *The Prince* resonated very well with what Mr. Munger has been advocating for years.

I reproduce here an excerpt from Sample’s book which deals with the law of the higher good:

“Let me clarify the most fundamental misunderstanding. Machiavelli was not an immoral or even an amoral man; as mentioned earlier, he had a strong set of moral principles. But he was driven by the notion of a higher good: an orderly state in which citizens can move about at will, conduct business, safeguard their families and possessions, and be free of foreign intervention or domination. Anything which could harm this higher good, Machiavelli argued, must be opposed vigorously and ruthlessly. Failure to do so out of either weakness or kindness was condemned by Machiavelli as being contrary to the interests of the state, just as it would be contrary to the interests of a patient for his surgeon to refuse to perform a needed operation out of fear that doing so would inflict pain on the patient.”

The law of the higher good is a terribly useful model for leaders because it forces them to think about things from a totally different perspective.

Here’s a hypothetical situation to ponder about:

You are in charge of running a retail store and one of your cashiers, an elderly woman, is caught committing a minor embezzlement. Fearing that she might be dismissed, she approaches you to plead forgiveness. She tells you that this is the first time she embezzled money from the company and promises that she’ll never do it again. She tells you about her sad situation, namely that her husband is very ill and that she was going to use the money to buy medicines for him. She becomes extremely emotional and your heart is melting. What do you do?

Something similar to the above situation was described by Mr. Munger in a talk given by him. He used two models to produce his answer. The first model was probability. Mr. Munger implores you to reduce the problem to the mathematics of Fermat/Pascal by asking the question: How likely is it that the old woman’s statement, “I’ve never done it before, I’ll never do it again” is true?

Note that this question has nothing whatsoever to do with the circumstances in this particular instance of embezzlement. Rather, Munger is relying on his knowledge of the

theory of probability. He asks: "If you found 10 embezzlements in a year, how many of them are likely to be first offences?"

The possible actions are: (1) She is lying and you fire her (good outcome – because it cures the problem and sends the right signals); (2) She is telling the truth and you fire her (bad outcome for her but good outcome for system integrity); (3) She is lying and you pardon her (bad outcome for system integrity); and (4) She is telling the truth and you pardon her (bad outcome for system integrity because it will send the wrong signal that its ok to embezzle once).

Weighed with probabilities, and after considering signalling effects of your actions on other people's incentives and its effect on system integrity, its clear that the woman should be fired.

Looked this way, this is not a legal problem or an ethical problem. Its an arithmetical problem with a simple solution. This extreme reductionism of practical problems to a fundamental discipline (in this case mathematics), is, of course, the hallmark of the Munger way of thinking and living.

So, from a leader's perspective, it's more important to have the right systems with the right incentives in place, rather than trying to be fair to one person – even if that person is the leader or someone close to the leader.

The logic is that leaders must look at such situations from their civilization's point of view rather than the viewpoint of an individual. If we create systems which encourage embezzlements, or tolerate such systems, we'll ruin our civilization. If we don't punish the woman, the idea that its ok to do minor embezzlement once in a while, will spread because of incentive effects, and social proof (everyone's doing it so its ok). And we cannot let that idea spread because that will ruin our civilization. Its that simple.

6. Two Questions Everyone Asks Themselves When They Meet You

People everywhere differentiate each other by liking (warmth, trustworthiness) and by respecting (competence, efficiency).

Essentially they ask themselves: (1) Is this person warm? and (2) Is this person competent?

The “warmth dimension captures traits that are related to perceived intent, including friendliness, helpfulness, sincerity, trustworthiness and morality, whereas the competence dimension reflects traits that are related to perceived ability, including intelligence, skill, creativity and efficacy.”

“In sum, although both dimensions are fundamental to social perception, warmth judgments seem to be primary, which reflects the importance of assessing other people’s intentions before determining their ability to carry out those intentions.”

Like all perception, social perception reflects evolutionary pressures. In encounters with conspecifics, social animals must determine, immediately, whether the ‘other’ is friend or foe (i.e. intends good or ill) and, then, whether the ‘other’ has the ability to enact those intentions. New data confirm these two universal dimensions of social cognition: warmth and competence. Promoting survival, these dimensions provide fundamental social structural answers about competition and status. People perceived as warm and competent elicit uniformly positive emotions and behavior, whereas those perceived as lacking warmth and competence elicit uniform negativity. People classified as high on one dimension and low on the other elicit predictable, ambivalent affective and behavioral reactions. These universal dimensions explain both interpersonal and intergroup social cognition.

7. Poaching Stars is a Terrible Idea to Improve Performance

In an effort to improve performance we often turn to the simple answer of trying to hire a star from another organization. This sounds like a great idea, is hard to argue with, and offers the promise of an instant performance boost.

In practice, most of the benefits turn out to be illusory.

The question is why?

One reason is that we think of the person as an isolated system when in reality they are not. The surrounding team, culture, and environment can amplify their success.

In his wonderful book, Think Twice: Harnessing the Power of Counterintuition, Michael Mauboussin explains:

A star's performance relied to some degree on the people, structure, and norms around him—the system. Analyzing results requires sorting the relative contributions of the individual versus the system, something we are not particularly good at. When we err, we tend to overstate the role of the individual.

This mistake is consequential because organizations routinely pay big bucks to lure high performers, only to be sorely disappointed. In one study, a trio of professors from Harvard Business School tracked more than one thousand acclaimed equity analysts over a decade and monitored how their performance changes as they switched firms. Their dour conclusion, "When a company hires a star, the star's performance plunges, there is a sharp decline in the functioning of the group or team the person works with, and the company's market value falls." The hiring organization is let down because it failed to consider systems-based advantages that the prior employer supplied, including firm reputation and resources. Employers also underestimate the relationships that supported previous success, the quality of the other employees, and a familiarity with past processes. What's happening is a common mistake — we're focusing on an isolated part of a complex adaptive system without understanding how that part contributes to the overall system dynamics.

For more information read the Harvard Business Review article: *The Risky Business of Hiring Stars*.

8. Learning Effectively From Experience: Distinguishing High from Low Performers

High performers learn from both success and failure making small adjustments.

Conversely, low performers learned more from success.

Learning effectively from experience is a daunting task for any organism. For every good or bad outcome, there are an immense number of potential causes and associations to be considered. For many decisions, it can be nearly impossible to pick out the few relevant factors from the many irrelevant factors, even with extensive experience. A major stumbling block for learning in these multi-dimensional environments is the tendency to form spurious beliefs: i.e., to attribute a causal role to factors that have no actual bearing on the outcome.

The formation of spurious beliefs is universal, from Skinner's observations of superstitious pigeons [1] to an athlete's belief in a lucky hat. In some situations, these beliefs are essentially harmless; by-products of learning mechanisms, but in other settings their impact can be severe. For example, spurious associations can have literal life-or-death consequences when they affect the complex decisions made by physicians. These expert decision-makers must extract and distill relevant features from a myriad of tests, symptoms, and personal histories, and employ these features to make critical medical decisions. Consequently, it is important to understand how spurious associations form and how they can bias subsequent decisions.

Spurious learning and false belief formation happens when the dorsolateral prefrontal cortex fails to distinguish correctly between important and unimportant associations.

The authors conclude:

High performers learned from both successes and failures, and made smaller rule adjustments after feedback. Conversely, low performers learned disproportionately from successes, and made larger rule adjustments ...

Taken together, the behavioral and neuroimaging results suggest that success-chasing and confirmation bias may underlie the relative pervasiveness of premature, asymmetric learning and the resultant poor performance of the majority of physician subjects in the present study. The general human bias towards confirmation over disconfirmation in hypothesis-testing has been extensively documented in a variety of non-medical contexts, such as the Wason Card Task. Conversely, the necessity for disconfirmation learning in empirical investigations is a key principle identified by the philosopher of science, Karl Popper [28]. Conceivably, providing medical professionals with formal training in disconfirmation learning could improve their ability to learn effectively from clinical experience in real-world settings. Exploring this possibility would be an important area for future research.

In conclusion, the results of this study show distinct patterns of learning, both behaviorally and neurally, between effective and ineffective learners among physicians making decisions in a medically framed learning task. The tendency to chase successes and ignore failures provides a simple computational model of how spurious beliefs might be formed, and how different individuals seeing similar data might learn very different sets of associations. The neural differences observed could conceivably be developed into useful biomarkers for essential differences in individual learning styles. These may in turn prove useful in identifying those individuals who can resist the impulse to chase successes, and hence learn most effectively from experience. Finally, we note that although this study focused upon the specific case of medical decision-making, the findings may be also be relevant to many other fields in which experts must make high-stakes decisions by drawing upon personal experience.

Abstract:

Accurate associative learning is often hindered by confirmation bias and success-chasing, which together can conspire to produce or solidify false beliefs in the decision-maker. We performed functional magnetic resonance imaging in 35 experienced physicians, while

they learned to choose between two treatments in a series of virtual patient encounters. We estimated a learning model for each subject based on their observed behavior and this model divided clearly into high performers and low performers. The high performers showed small, but equal learning rates for both successes (positive outcomes) and failures (no response to the drug). In contrast, low performers showed very large and asymmetric learning rates, learning significantly more from successes than failures; a tendency that led to sub-optimal treatment choices. Consistently with these behavioral findings, high performers showed larger, more sustained BOLD responses to failed vs. successful outcomes in the dorsolateral prefrontal cortex and inferior parietal lobule while low performers displayed the opposite response profile. Furthermore, participants' learning asymmetry correlated with anticipatory activation in the nucleus accumbens at trial onset, well before outcome presentation. Subjects with anticipatory activation in the nucleus accumbens showed more success-chasing during learning. These results suggest that high performers' brains achieve better outcomes by attending to informative failures during training, rather than chasing the reward value of successes. The differential brain activations between high and low performers could potentially be developed into biomarkers to identify efficient learners on novel decision tasks, in medical or other contexts.

9. Situations Matter

*"We're easily seduced by the notion of stable character.
So much of who we are, how we think, and what we do is
driven by the situations we're in, yet we remain blissfully unaware of it."*
— Sam Sommers

Situations Matter is an excellent book that should give you a leg up in life.

One of the lessons of modern psychological research is that 'the situation' we find ourselves in influences us. If you've ever wondered about why you are not as independent-minded as you think or about the difference between men and women this is a great book.

A summary paragraph:

So much of how we see and interact with the social universe around is shaped by our immediate context. ... seemingly trivial aspects of daily situations determine whether we keep to ourselves or get involved in the affairs of others, whether we follow a group or stake out on an independent path, why we're drawn to certain people and away from others.

As Sam Sommers points out, "once you start paying attention to situations there's no going back." Sommers argues, "People are easy to see. They're tangible. Context is harder: it's an abstract, nebulous concept, a backdrop that can be downright invisible. Precisely because situations are difficult to see, effort is required to recognize their influence."

The context in which we make decisions matters. Stress might mean we don't consider all the options or we become paralyzed. Focusing on an outcome means we miss what's possible. When we're rushed, we're not paying attention to obvious signals and warnings. It's hard to make good decisions when you have blind spots.

If you want to understand why someone made a particular decision or is behaving in a certain way, put yourself in their shoes. If you see what they see, suddenly the behaviour or decision becomes rational.

Not only are others blind to the larger context but we are often blind to their context. Only by zooming out and looking at the situations through the eyes of multiple people, can you begin to acquire perspective. And perspective is the key to removing blind-spots.

10. Richard Feynman on Why Questions

In this beautiful video, [Richard Feynman](#) on the nature of why questions and how they help us understand the world.

Interviewer: If you get hold of two magnets, and you push them, you can feel this pushing between them. Turn them around the other way, and they slam together. Now, what is it, the feeling between those two magnets?

Feynman: What do you mean, "What's the feeling between the two magnets?"

There's something there, isn't there? The sensation is that there's something there when you push these two magnets together.

Listen to my question. What is the meaning when you say that there's a feeling? Of course, you feel it. Now, what do you want to know?

What I want to know is what's going on between these two bits of metal?

They repel each other.

What does that mean, or why are they doing that, or how are they doing that? I think that's a perfectly reasonable question.

Of course, it's an excellent question. But the problem, you see, when you ask why something happens, how does a person answer why something happens? For example, Aunt Minnie is in the hospital. Why? Because she went out, slipped on the ice, and broke her hip. That satisfies people. It satisfies, but it wouldn't satisfy someone who came from another planet and knew nothing about why when you break your hip do you go to the hospital. How do you get to the hospital when the hip is broken? Well, because her husband, seeing that her hip was broken, called the hospital up and sent somebody to get her. All that is understood by people. And when you explain a why, you have to be in some framework that you allow something to be true. Otherwise, you're perpetually asking why. Why did the husband call up the hospital? Because the husband is interested in his wife's welfare. Not always, some husbands aren't interested in their wives' welfare when they're drunk, and they're angry.

"But the problem, you see, when you ask why something happens, how does a person answer why something happens?"

— Richard Feynman

And you begin to get a very interesting understanding of the world and all its complications. If you try to follow anything up, you go deeper and deeper in various directions. For example, if you go, "Why did she slip on the ice?" Well, ice is slippery. Everybody knows that, no problem. But you ask why is ice slippery? That's kinda curious. Ice is extremely slippery. It's very interesting. You say, how does it work? You could either say, "I'm satisfied that you've answered me. Ice is slippery; that explains it," or you could go on and say, "Why is ice slippery?" and then you're involved with something, because there aren't many things as slippery as ice. It's not very hard to get greasy stuff, but that's sort of wet and slimy. But a solid that's so slippery? Because it is, in the case of ice, when you stand on it (they say) momentarily the pressure melts the ice a little bit so you get a sort of instantaneous water surface on which you're slipping. Why on ice and not on other things? Because water expands when it freezes, so the pressure tries to undo the expansion and melts it. It's capable of melting, but other substances get cracked when they're freezing, and when you push them they're satisfied to be solid.

Why does water expand when it freezes and other substances don't? I'm not answering your question, but I'm telling you how difficult the why question is. You have to know what it is that you're permitted to understand and allow to be understood and known, and what it is you're not. You'll notice, in this example, that the more I ask why, the deeper a thing is, the more interesting it gets. We could even go further and say, "Why did she fall down when she slipped?" It has to do with gravity, involves all the planets and everything else. Nevermind! It goes on and on. And when you're asked, for example, why two magnets

repel, there are many different levels. It depends on whether you're a student of physics or an ordinary person who doesn't know anything. If you're somebody who doesn't know anything at all about it, all I can say is the magnetic force makes them repel, and that you're feeling that force.

You say, "That's very strange, because I don't feel a kind of force like that in other circumstances." When you turn them the other way, they attract. There's a very analogous force, electrical force, which is the same kind of a question, that's also very weird. But you're not at all disturbed by the fact that when you put your hand on a chair, it pushes you back. But we found out by looking at it that that's the same force, as a matter of fact (an electrical force, not magnetic exactly, in that case). But it's the same electric repulsions that are involved in keeping your finger away from the chair because it's electrical forces in minor and microscopic details. There are other forces involved, connected to electrical forces. It turns out that the magnetic and electrical force with which I wish to explain this repulsion in the first place is what ultimately is the deeper thing that we have to start with to explain many other things that everybody would just accept. You know you can't put your hand through the chair; that's taken for granted. But that you can't put your hand through the chair, when looked at more closely, why, involves the same repulsive forces that appear in magnets. The situation you then have to explain is why, in magnets, it goes over a bigger distance than ordinarily. There it has to do with the fact that in iron all the electrons are spinning in the same direction, they all get lined up, and they magnify the effect of the force 'til it's large enough, at a distance, that you can feel it. But it's a force which is present all the time and very common and is a basic force of almost – I mean, I could go a little further back if I went more technical – but on an early level I've just got to tell you that's going to be one of the things you'll just have to take as an element of the world: the existence of magnetic repulsion, or electrical attraction, magnetic attraction. I can't explain that attraction in terms of anything else that's familiar to you. For example, if we said the magnets attract like rubber bands, I would be cheating you. Because they're not connected by rubber bands. I'd soon be in trouble. And secondly, if you were curious enough, you'd ask me why rubber bands tend to pull back together again, and I would end up explaining that in terms of electrical forces, which are the very things that I'm trying to use the rubber bands to explain. So I have cheated very badly, you see. So I am not going to be able to give you an answer to why magnets attract each other except to tell you that they do. And to tell you that that's one of the elements in the world – there are electrical forces, magnetic forces, gravitational forces, and others, and those are some of the parts. If you were a student, I could go further. I could tell you that the magnetic forces are related to the electrical forces very intimately, that the relationship between the gravity forces and electrical forces remains unknown, and so on. But I really can't do a good job, any job, of explaining magnetic force in terms of something else you're more familiar with, because I don't understand it in terms of anything else that you're more familiar with.

11. Mindless Eating: Why We Eat More Than We Think

Mindless Eating: Why We Eat More Than We Think will change the way you think about your next meal.

According to eating behavior expert Brian Wansink the mind makes food-related decisions, more than 200 a day, and many of them without pause for actual thought. In *Mindless Eating*, Wansink argues that we don't have to change what we eat as much as how we eat. Make no mistake, this isn't a diet book.

Wansink says "This book is not about dietary extremism—just the opposite. It's about reengineering your environment so that you can eat what you want without guilt and without gaining weight. It's about reengineering your food life so that it is enjoyable."

The research summaries are entertaining. Take the study of how much people ate when their plates were literally bottomless. "It seems," Wansink writes, "that when estimating almost anything—such as weight, height, brightness, loudness, sweetness, and so on—we consistently under-estimate things as they get larger."

"While most Americans stop eating when they're full, those in leaner cultures stop eating when they're no longer hungry." Not only that, unlike our (leaner) European friends, we tend to have bigger package sizes (and bigger kitchens), which means we end up eating (or pouring) more — "Because big packages (like big portions) suggest a consumption norm—what is appropriate or normal to use or eat."

The problem is we're all tricked by our environment. We think others could be fooled by something as simple as a bigger plate, but we never think we are fooled. That is what gives mindless eating so much power over us—we're not aware it's happening. Wansink's approach is to change the environment.

Wansink believes that warehouse clubs are bad for our health. He also explains why you should leave empty wine glasses on the table, why Cinnabon stores are positioned beside stores that don't sell food, how Subway is bad for your health, and why you should be the last person to start eating.

"Regardless of how well we think we are tuned into our eating decisions, we will serve 25% to 35% more on a larger plate than a smaller plate." Don't think it makes a difference? 150 extra-calories a day is up to 15 pounds a year.

11. Owning up to Your Ignorance by Saying “I Don’t Know”

When was the last time you admitted you didn’t know something?

Saying ‘I don’t know’ is hard. We can be so resistant to it that we end up not even knowing what we don’t know. This is dangerous. When you don’t know what you don’t know you’re clueless as to how to minimize those gaps in your knowledge. This could hinder your ability to succeed in business and life.

Furthermore, if you’re in a position to mentor or teach others, they probably expect you to know your blind spots. People look to you for knowledge and ideas. But you might be disseminating ignorance instead. And who needs more of that in a world full of it?

Justin Landis wrote an interesting blog [post](#) in response to a Freakonomics podcast “Why Is ‘I Don’t Know’ So Hard to Say?”

The highlight:

[T]hose of us who live in the business world are certainly incentivized to focus on what we know over what we don’t know. And whether we’re talking about closing a deal with an important client or simply competing with peers for a limited number of positions in a given field, this holds true. By highlighting what we know and tactfully hiding what we don’t, we present the illusion of mastery, and this is thought to (and generally does) inspire confidence in our ability to execute. The incentive here is clear, and the results are pretty clear as well, at least in my experience. The unintended consequence is that while we’re all focusing on what we know and making sure others are aware of those things, there is still a lot that we don’t know. In some cases, we may not even really know what we don’t know. And this is the most dangerous place to be in.

Not knowing what you don’t know is dangerous indeed. In this position, you are clueless as to how to minimize gaps in your knowledge, which could hinder your ability to excel in business and in life. Furthermore, if you are in a position to teach, mentor, and/or coach others, then people are looking to you for knowledge and ideas. But instead of spreading knowledge and idea, you’d be disseminating false information and ignorance. And who needs more ignorance in a world that’s already full of it?

If I asked you if you knew how your cellphone works, you’d probably say yes, right? But if I asked you why your screen reacts to the touch of your fingertips or how the power button turns on your phone, what would you say? The [illusion of explanatory depth](#) (IOED) is a term that was first coined by Leonid Rozenblit and Frank Keil in their 2002 research paper, [The misunderstood limits of folk science: an illusion of explanatory depth](#). From the abstract:

[People feel they understand complex phenomena with far greater precision, coherence, and depth than they really do; they are subject to an illusion—an illusion of explanatory depth. The illusion is far stronger for explanatory knowledge than many other kinds of knowledge, such as that for facts, procedures or narratives. The illusion for explanatory knowledge is most robust where the environment supports real-time explanations with visible mechanisms.

But consider this: “[Fake it ‘til you make it](#)” can be seen as the internal battle cry of people who feel out of their depth. However, despite their insecurities, they still pursue what they desire. This imaginary mask of confidence that hides their shortcomings becomes the buoy that keeps them afloat. Oftentimes, they end up doing what they set out to do and exceed expectations. Sometimes that individual can morph into the person they were pretending to be in the first place. It’s an idealistic outcome, but it does happen.

Needless to say, we must not forget the potentially disastrous outcomes that occur when this transformation doesn’t happen and they go on fooling others and themselves instead. If we acknowledge our ignorance, an empty space in our knowledge that needs to be filled, we need to carefully consider how we say “I don’t know”. Right now, I don’t have the answer but I will find out for you. I don’t know but I know someone that does. Or simply, I’m

sorry, but as much as I wish I could help you, I'm just not the right person to solve this problem. I don't want to put your project in jeopardy.
Depending on who you are, facing this reality can either be uncomfortable, terrifying or liberating.

12. The Filter Bubble — What the Internet is Hiding From You

In case you're interested, we have another article on The Filter Bubble [here](#).

Just “googling it” might not be such a great idea after all

The Filter Bubble, by Eli Pariser, puts forth an argument that we're increasingly trapped inside an algorithm that filters our news based on what it thinks is best for us. In this case, IT is an algorithm.

Computers and the algorithms they run are increasingly aware of the things we seem to like. They learn from what we click on and tailor results so we get more of what we like and less of what we don't like. The equivalent would be parents giving their kids only sugar because that's what they seem to like. Only parents know better, so they feed their kids what they need first with a sprinkling of what they want. Algorithms don't. This means that two people googling the same thing are likely to see different results.

The problem with this, Pariser argues, is that you're not making a conscious choice to have your results filtered — it happens without your knowledge or consent. And that causes a whole host of issues, of which Pariser is primarily concerned with the social and political implications.

When technology's job is to show you the world, it ends up sitting between you and reality, like a camera lens.

“If we want to know what the world really looks like,” Pariser writes, “we have to understand how filters shape and skew our view of it.” It's useful to borrow from nutrition to illustrate this point:

Our bodies are programmed to consume fat and sugars because they're rare in nature. Thus, when they come around, we should grab them. In the same way, we're biologically programmed to be attentive to things that stimulate: content that is gross, violent, or sexual and that gossip which is humiliating, embarrassing, or offensive. If we're not careful, we're going to develop the psychological equivalent of obesity. We'll find ourselves consuming content that is least beneficial for ourselves or society as a whole.

Consider for a moment where we are headed. If Google knows that I'm a democrat or republican they *could* now add a filter to my news to show me only the stories I'm predisposed to agree with. Based on their guess as to my education level, they may then tailor the article's words and language to maximize its impact on me. In this world, I only see things I agree with and writing that I easily comprehend and that's a problem. Google might know that I don't read anything about Republican tax cuts or democratic spending so they might just filter those articles out. Reality, as I see it, becomes what the lens shows me.

“If you're not paying for something, you're not the customer; you're the product being sold.”

— Andrew Lewis

When asked about the prospects for important but unpopular news, Media Lab's Nicholas Negroponte smiled. On one end of the spectrum, he said is sycophantic personalization — “you're so great and wonderful, and I'm going to tell you exactly what you want to hear.”

On the other end is the parental approach: “I'm going to tell you this whether you want to hear this or not, because you need to know.” Currently, he argues, we're headed in sycophantic direction.

Whether you believe the book's conclusions are wholly convincing or not, it is worth thinking about. If nothing else, it is thought-provoking.

(If you want a search engine that won't “track you” try [DuckDuckGo.com](#))

13. Does Experience Make You an Expert?

In Experience and validity of clinical judgment: The illusory correlation, Robyn Dawes explores the relationship between experience and accuracy.

There is research about the relationship between experience and diagnostic and predictive accuracy, and about the validity of interviewing people to find out what they are like. Garb has recently summarized the research on experience and accuracy. There is no relationship between years of clinical experience and accuracy of judgment. A report of a task force of the American Psychological Association convened in the early 1980s noted that there was no evidence that professional competence is related to years of professional experience.

And yet we seek experienced people to be our teachers, executives, and political leaders. Ben Franklin is oft quoted as saying “experience is the best teacher,” the second clause reads “and fools will learn from no other.” Only Franklin didn’t say “the best teacher” he said “dear teacher,” which was clearly intended to mean expensive.

The 10,000-hour rule, popularized by Malcolm Gladwell and based on Anders Ericsson’s study, *The Role of Deliberate Practice in the Acquisition of Expert Performance*, states that in order to become an expert, one must have 10,000 hours of deliberate practice under their belts. This has been highly disputed by many, including Ericsson himself. There’s no question that practice is necessary for improvement, but 10,000 hours isn’t a magic number that wields the power of universal application.

Something else to ponder: why is it that we often forget to account for the length of time that an expert has been out of practice in their field?

So does experience really make you an expert? What does it actually mean to be one? It turns out, we don’t learn from experience in many contexts.

The analysis of what we learn and why we learn it, however, quickly yields sobriety about embracing generalizations about the effect of experience on learning across all contexts. For example, learning to sit in a chair, become a chess grandmaster, make a correct medical diagnosis, or avoid a war are quite different processes. The word “learning” is, of course, common to all, but close examination reveals that it means little more than that someone with no experience whatsoever could not accomplish any of these tasks.

Dawes illuminates this highly contrarian idea through quite unremarkable human behaviours like sitting in a chair and driving.

What then are the differences? First, consider sitting in a chair. It is a motor skill. It is done automatically. It does not involve any conscious hypotheses. It is clearly learned through early experience that provides immediate feedback about failure. Finally, it is not taught in the sense that one person conveys a verbal or mathematical description to another about how to do it. (In fact an amusing exercise is to attempt to write such a description, convince somebody else to follow your instructions explicitly—and then watch the person fail.) Driving a car has many similar characteristics. For example, steering it in a straight line is accomplished by very tiny discrete adjustments of the steering wheel that are not accomplished consciously (Ehrlich, 1966). (The “weaving” behavior of drunk drivers is often due to the impairment of these movements, rather than to any visual problem.) The skills needed to perform these slight movements are attained only through experience driving; in fact, most complete novices on the first driving lesson alternate between going toward the ditch and almost crossing the center line—much to the surprise and consternation of their novice teachers, who themselves may be unaware of their own “tremorous” movements of the steering wheel. As with sitting in a chair, explicit verbal instructions to someone else about exactly how to drive a car could result in disaster for the person who follows them rigidly.

Consider the curious thing that happened during the Paris Wine Tasting of 1976, alternatively known as the Judgement of Paris (its name was inspired by a story in Greek

mythology). During this blind taste competition, French wine experts judged ten different reds and ten different whites. Contrary to the strongly held belief that France produced the finest wines, it was the California wines that received the highest scores. Not only did the shocking results of the competition call into question the supposed superiority of French wine, but it served as a reason for people to wonder what authority an expert had over a casual wine drinker.

Abstract of Experience and validity of clinical judgment: The illusory correlation
Mental health experts often justify diagnostic and predictive judgments on the basis of "years of experience" with a particular type of person. Justification by experience is common in legal settings, and can have profound consequences for the person about whom such judgments are made. However, research shows that the validity of clinical judgment and amount of clinical experience are unrelated. The role of experience in learning varies as a function of what is to be learned. Experiments show that learning conceptual categories depends upon: (1) the learner's having clear hypotheses about the possible rule for category membership prior to receiving feedback about which instances belong to the category, and, (2) the systematic nature of such feedback, especially about erroneous categorizations. Since neither of these conditions is satisfied in clinical contexts in psychology, the subsequent failure of experience per se to enhance diagnostic or predictive validity is unsurprising. Claims that "I can tell on the basis of my experience with people of a particular type (e.g., child abusers) that this person is of that type (e.g., a child abuser)" are simply invalid.

14. Become A Learning Machine

When successful people from different fields offer the same advice, I listen. Often they have different vocabulary around an idea, but when you break it down you realize they're talking about the same thing.

Below is an example of Charlie Munger, Carol Dweck, and Susan Cain, offering the same core advice: Become a Learning Machine.

If you want to go to bed smarter than you woke up, you need to learn something new each day. It doesn't matter how smart you are today; what matters it that you learn something new and useful. If you can simply repeat that day after day, you will find that you outperform others.

It can be hard to grasp this concept because the differences at first are small. Only as the days turn into weeks, the weeks into months, the months into years, and the years into decades will you look back and wonder how it happened.

Charlie Munger:

I constantly see people rise in life who are not the smartest, sometimes not even the most diligent, but they are learning machines. They go to bed every night a little wiser than they were when they got up and boy does that help, particularly when you have a long run ahead of you.

Carol Dweck says:

You have to apply yourself each day to becoming a little better. By applying yourself to the task of becoming a little better each and every day over a period of time, you will become a lot better.

And this tidbit from Susan Cain, also fits:

...identify the tasks or knowledge that are just out of your reach, strive to upgrade your performance, monitor your progress, and revise accordingly.

15. Why Nations Fail

An interesting opinion piece by Thomas Friedman in the New York Times on the new book Why Nations Fail, co-authored by the M.I.T. economist Daron Acemoglu and the Harvard political scientist James A. Robinson.

The more you read it, the more you appreciate what a fool's errand we're on in Afghanistan and how much we need to totally revamp our whole foreign aid strategy. But most intriguing are the warning flares the authors put up about both America and China.

Why Nations Fail argues the key differentiator between countries is their institutions. Nations fail when institutions concentrate power in the hands of only a few.

From Why Nations Fail:

Inclusive economic institutions that enforce property rights, create a level playing field, and encourage investments in new technologies and skills are more conducive to economic growth than extractive economic institutions that are structured to extract resources from the many by the few.

"Inclusive economic institutions, are in turn supported by, and support, inclusive political institutions," which "distribute political power widely in a pluralistic manner and are able to achieve some amount of political centralization so as to establish law and order, the foundations of secure property rights, and an inclusive market economy."

Back to Friedman in the Times

The lesson of history, the authors argue, is that you can't get your economics right if you don't get your politics right, which is why they don't buy the notion that China has found the magic formula for combining political control and economic growth.

"Our analysis," says Acemoglu, "is that China is experiencing growth under extractive institutions — under the authoritarian grip of the Communist Party, which has been able to monopolize power and mobilize resources at a scale that has allowed for a burst of economic growth starting from a very low base," but it's not sustainable because it doesn't foster the degree of "creative destruction" that is so vital for innovation and higher incomes.

"Sustained economic growth requires innovation," the authors write, "and innovation cannot be decoupled from creative destruction, which replaces the old with the new in the economic realm and also destabilizes established power relations in politics."

"Unless China makes the transition to an economy based on creative destruction, its growth will not last," argues Acemoglu. But can you imagine a 20-year-old college dropout in China being allowed to start a company that challenges a whole sector of state-owned Chinese companies funded by state-owned banks? he asks.

Afghanistan was a fool's errand

The post-9/11 view that what ailed the Arab world and Afghanistan was a lack of democracy was not wrong, said Acemoglu. What was wrong was thinking that we could easily export it. Democratic change, to be sustainable, has to emerge from grassroots movements, "but that does not mean there is nothing we can do," he adds.

As for America

Acemoglu worries that our huge growth in economic inequality is undermining the inclusiveness of America's institutions, too. "The real problem is that economic inequality, when it becomes this large, translates into political inequality."

16. A Primer on Strategy

There are many good reasons to read Good Strategy Bad Strategy by Richard Rumelt. You may be frustrated by the state of your organization's strategy. You may be interested in identifying the characteristics of good strategy. Or you may want to learn how to identify the elements of a bad strategy.

A leader's most important responsibility is identifying the biggest challenges to forward progress and devising a coherent approach to overcoming them. In contexts ranging from corporate direction to national security, strategy matters. Yet we have become so accustomed to strategy as exhortation that we hardly blink an eye when a leader spouts slogans and announces high-sounding goals, calling the mixture a "strategy."

Complexity

"A hallmark of mediocrity and bad strategy," Rumelt writes, "is unnecessary complexity—a flurry of fluff masking an absence of substance." Most bad strategies are nothing more than statements of desire. And if you read them closely, the goals often contradict one another.

This book should be required reading for managers and executives alike.

The Strategy Retreat

I'm sure this excerpt sounds familiar to many of you:

The event was a "strategy retreat." The CEO had modeled it on a similar event at British Airways he had attended several years before. About two hundred upper-level managers from around the world gathered in a hotel ballroom where top management presented a vision for the future: to be the most respected and successful company in their field. There was a specially produced motion picture featuring the firm's products and services being used in colorful settings around the world. There was an address by the CEO accompanied by dramatic music to highlight the company's "strategic" goals: global leadership, growth, and high shareholder return. There were breakouts into smaller groups to allow discussion and buy-in. There was a colorful release of balloons. There was everything but strategy.

Good strategy is the exception not the rule. Rumelt argues that the bad strategy problem is only growing. Even worse, more and more leaders think they have a strategy when they do not—they have a bad strategy. Bad strategy, "ignores the power of choice and focus, trying instead to accommodate a multitude of conflicting demands and interests." Sounds familiar?

What is a bad strategy?

Bad strategy is long on goals and short on policy or action. It assumes that goals are all you need. It puts forward strategic objectives that are incoherent and, sometimes, totally impracticable. It uses high-sounding words and phrases to hide these failings.

Underperformance

When a leader characterizes the challenge as underperformance, it sets the stage for bad strategy. Underperformance is a result. The true challenges are the reasons for the underperformance.

Good Strategy

Good strategy is not just "what" you are trying to do. It is also "why" and "how" you are doing it. ... Good strategy requires leaders who are willing and able to say no to a wide variety of actions and interests. Strategy is at least as much about what an organization does not do as it is about what it does.

Strategy is not vision or ambition

Despite the roar of voices wanting to equate strategy with ambition, leadership, "vision," planning, or the economic logic of competition, strategy is none of these. The core of strategy work is always the same: discovering the critical factors in a situation and designing a way of coordinating and focusing actions to deal with those factors. A leader's most important responsibility is identifying the biggest challenges to forward progress and

devising a coherent approach to overcoming them. In contexts ranging from corporate direction to national security, strategy matters.

The Three Elements of Strategy

The kernel of a strategy contains three elements: a diagnosis, a guiding policy, and coherent action. The guiding policy specifies the approach to dealing with the obstacles called out in the diagnosis. It is like a signpost, marking the direction forward but not defining the details of the trip. Coherent actions are feasible coordinated policies, resource commitments, and actions designed to carry out the guiding policy.

Coherence of design

A good strategy doesn't just draw on existing strength; it creates strength through the coherence of its design. Most organizations of any size don't do this. Rather, they pursue multiple objectives that are unconnected with one another or, worse, that conflict with one another.

Coordination is costly and hard

Coordination is costly, because it fights against the gains to specialization, the most basic economies in organized activity. To specialize in something is, roughly speaking, to be left alone to do just that thing and not be bothered with other tasks, interruptions, and other agents' agendas. As is clear to anyone who has belonged to a coordinating committee, coordination interrupts and de-specializes people.

Good strategy is surprising

Most complex organizations spread rather than concentrate resources, acting to placate and pay off internal and external interests. Thus, we are surprised when a complex organization, such as Apple or the U.S. Army, actually focuses its actions. Not because of secrecy, but because good strategy itself is unexpected.

Focus, however, is hard. It means saying no to individuals, groups, and even entire lines of business.

The inside view describes the fact that people tend to see themselves, their group, their project, their company, or their nation as special and different.

Increasing value ...

In particular, increasing value requires a strategy for progress on at least one of four different fronts: deepening advantages, broadening the extent of advantages, creating higher demand for advantaged products or services, or strengthening the isolating mechanisms that block easy replication and imitation by competitors.

Unfinished Thought

As I was reading this book I kept wondering why organizations were so reluctant to employ a strategy. All of this thinking reminded me of another book I had read a few years back on strategy called The Strategy Paradox.

What is the paradox?

The most profitable strategies are "extreme" strategies that commit companies to positions of either product differentiation or cost leadership. These extreme positions expose firms to a greater likelihood of bankruptcy by increasing the strategic risk they face.

Consequently, the strategies likeliest to succeed are also likeliest to fail. That is the strategy paradox.

At first I thought that maybe organizations avoided good strategy simply because it was complicated and involved hard choices. The more I thought about it, however, the more I settled on the fact that people avoid good strategies because they don't want to be wrong. When Steve Jobs took over Apple, he did the unexpected.

What he did was both obvious and, at the same time, unexpected. He shrunk Apple to a scale and scope suitable to the reality of its being a niche producer in the highly competitive personal computer business. He cut Apple back to a core that could survive. Steve Jobs talked Microsoft into investing \$150 million in Apple, exploiting Bill Gates's concerns about what a failed Apple would mean to Microsoft's struggle with the

Department of Justice. Jobs cut all of the desktop models—there were fifteen—back to one. He cut all portable and handheld models back to one laptop. He completely cut out all the printers and other peripherals. He cut development engineers. He cut software development. He cut distributors and cut out five of the company's six national retailers. He cut out virtually all manufacturing, moving it offshore to Taiwan. With a simpler product line manufactured in Asia, he cut inventory by more than 80 percent. A new Web store sold Apple's products directly to consumers, cutting out distributors and dealers.

What is remarkable about Jobs's turnaround strategy for Apple was how much it was "Business 101" and yet how much of it was unanticipated.

In May 1998, shortly after taking over Apple, Jobs explained the substance and coherence of his actions:

The product lineup was too complicated and the company was bleeding cash. A friend of the family asked me which Apple computer she should buy. She couldn't figure out the differences among them and I couldn't give her clear guidance, either. I was appalled that there was no Apple consumer computer priced under \$2,000. We are replacing all of those desktop computers with one, the Power Mac G3. We are dropping five of six national retailers—meeting their demand has meant too many models at too many price points and too much markup.

Jobs's actions were both focused and decisive and, in hindsight, correct. Everyone at the time was surprised because they expected the fluffy goals and vacuous promises typical of most executives. But Jobs's back-to-business 101 approach was correct. Jobs had a sick business and he needed to fix it.

While Jobs's turnaround at Apple was impressive it wouldn't enable Apple to become more than a niche player in an industry dominated by network effects. In 1998 Rumelt had a chance to ask Jobs "What is the strategy?" Jobs responded simply "I am going to wait for the next big thing."

This encounter struck Rumelt as different. Everywhere he went and everyone he talked to just spewed the same clichés about their strategy — network relationships, adopt best practices, etc.

Rumelt writes:

Jobs did not enunciate some simple-minded growth or market share goal. He did not pretend that pushing on various levers would somehow magically restore Apple to market leadership in personal computers. Instead, he was actually focused on the sources of and barriers to success in his industry—recognizing the next window of opportunity, the next set of forces he could harness to his advantage, and then having the quickness and cleverness to pounce on it quickly like a perfect predator. There was no pretense that such windows opened every year or that one could force them open with incentives or management tricks. He knew how it worked. He had done it before with the Apple II and the Macintosh and then with Pixar. He had tried to force it with NeXT, and that had not gone well. It would be two years before he would make that leap again with the iPod and then online music. And, after that, with the iPhone.

Steve Jobs's answer that day—"to wait for the next big thing"—is not a general formula for success. But it was a wise approach to Apple's situation at that moment, in that industry, with so many new technologies seemingly just around the corner.

In hindsight we know Jobs's strategy worked but it could have just as easily backfired. The turnaround might have failed and landed Apple, now the world's largest company, in bankruptcy. Apple's strategy at the time wasn't easy to like — in fact, many people thought he was wrong. I imagine that Jobs would have been ok with being wrong — he was more worried about being mediocre.

We equate strategy with success but they are different things.

Real strategies—*good strategies*—can be wrong. And we don't want to be wrong. We're playing not to lose rather than playing to win. We all know how it feels to make a mistake

— we'd rather watch other people make mistakes than make them ourselves. So we seek consensus because it's safe.

Yet consensus, when you think about it, is almost assured to fail. It's making everyone happy and alienating no one.

Consensus is the opposite of marshalling your resources towards a coordinated approach. And consensus, by definition, almost certainly assures a bad strategy because it doesn't make any choices. It's a sprinkle of this and a dash of that — it's something for everyone. Rather than risk being wrong, we hide behind puff that makes everyone happy. That's bad strategy.

The beauty of Good Strategy Bad Strategy is that it calls out the vast majority of public and private organizations that have horrible strategies. The bad news is that things are unlikely to change. After all, no one ever got fired for having a strategy to "increase the percentage of high school graduates." It's hard to argue with that as a goal but let's stop calling it a strategy.

There are plenty of good strategies out there. Lou Gestner developed one when he took over IBM in 1993 (for details see Gestner's book — Who Says Elephants Can't Dance?: Leading a Great Enterprise through Dramatic Change). He understood the problem and devised an approach that marshalled the organization towards dealing with the problem.

17. Do You Know What You Don't Know?

You probably don't know as much as you think you do. When put to the test, most people find they can't explain the workings of everyday things they think they understand. Don't believe me? Find an object you use daily (a zipper, a toilet, a stereo speaker) and try to describe the particulars of how it works. You're likely to discover unexpected gaps in your knowledge. In psychology, we call this cognitive barrier the illusion of explanatory depth. It means you think you fully understand something that you actually don't. We witness this all the time with the use of buzz words (think "strategic," "streamline," etc.).

While often used, the meaning of these words is usually unclear and masks gaps in our knowledge, "serving as placeholders that gloss concepts we don't fully understand."

These words are similar to Aphorisms in the sense that they stifle informed debate — you're expected to get the gist of what people mean and move on.

For example, several years ago, I attended a corporate meeting where the vice president spoke about streamlining business practices in the coming year. During the talk, executives around the room nodded in agreement. Afterward, though, many of them discussed what streamlining actually meant. None of the people who had nodded in agreement could exactly define the mechanics of how to streamline a business practice.

One tip:

Explain concepts to yourself as you learn them. Get in the habit of self-teaching. Your explanations will reveal your own knowledge gaps and identify words and concepts whose meanings aren't clear.

18. The Copernican Principle: How To Predict Everything

An old (1999) New Yorker article introduces us to J. Richard Gott III, a Princeton astrophysicist and some of his ideas on prediction. The core idea is that — despite what we'd like — we are not that special. So when we encounter something, we are unlikely to be doing so at a special time in its life. This is the Copernican Principle.

"On May 27, 1993, I looked up all the plays that were listed in The New Yorker—Broadway and Off Broadway plays and musicals—and called up each of the theatres and asked when each play had opened," Gott recalls. "I predicted how long each would run, based solely on how long it had been running already. Forty-four shows were playing at the time. So far, thirty-six of them have closed, all in agreement with my predictions of how long they would last. And the others, which are still running, are also within the range I'd predicted." *It must be said that Gott's predictions are, well, broad. He predicted, for instance, that "Marisol," which had been open for a week when he called the theatres, would close in less than thirty-nine weeks; it lasted 10 more days. To "Cats," which had then been running for three thousand eight hundred and eighty-five days, Gott assigned a longevity of not less than a hundred days and not more than four hundred and fourteen years.*

The significance of Gott's approach rests in its competence in addressing issues previously inaccessible to scientific inquiry, such as, say, trying to predict how long the human species will endure.

"As time goes on, you'll understand. What lasts, lasts; what doesn't, doesn't. Time solves most things. And what time can't solve, you have to solve yourself."

— Haruki Murakami

"My approach is based on the Copernican principle, which has been one of the most famous and successful scientific hypotheses in the history of science," Gott said. "It's named after Nicolaus Copernicus, who proved that the earth is not the center of the universe; and it's simply the idea that your location is not special. The more we've learned about the universe, the more non-special our location has looked. The earth is orbiting an ordinary star in an ordinary galaxy. The reason the Copernican principle works is that, of all the places for intelligent observers to be, there are, by definition, only a few special places and many non-special places. So you're simply more likely to be in one of the many non-special places."

The predictions that I make are based on applying this principle to time. I first thought of it in 1969. I'd just graduated from Harvard and was traveling around Europe, and I visited the Berlin Wall. People at the time wondered how long the Wall might last. Was it a temporary aberration, or a permanent fixture of modern Europe? Standing at the Wall in 1969, I made the following argument, using the Copernican principle. I said, Well, there's nothing special about the timing of my visit. I'm just travelling—you know, Europe on five dollars a day—and I'm observing the Wall because it happens to be here. My visit is random in time. So if I divide the Wall's total history, from the beginning to the end, into four quarters, and I'm located randomly somewhere in there, there's a fifty-percent chance that I'm in the middle two quarters—that means, not in the first quarter and not in the fourth quarter.

Let's suppose that I'm at the beginning of that middle fifty percent. In that case, one-quarter of the Wall's ultimate history has passed, and there are three-quarters left in the future. In that case, the future's three times as long as the past. On the other hand, if I'm at the other end, then three-quarters have happened already, and there's one-quarter left in the future. In that case, the future is one-third as long as the past.

The Wall was 8 years old at the time. "So I said to a friend, 'There's a fifty-percent chance that the Wall's future duration will be between two-thirds of a year (I believe this should be two and two-thirds of a year — i.e. $1/3$ of 8) and twenty-four years.' Twenty years later, in 1989, the Wall came down, within those two limits that I had predicted. I thought, maybe I should write this up."

Recently, it's come to be understood that systems may behave chaotically and therefore be unpredictable. You know, a butterfly in the Amazon can affect the weather thousands of miles away, that sort of thing. This has led some people to say that predicting the future of complex systems is impossible. Which is true if you are concerned with the precise specifics. To predict the name of the President of the United States in the year 2085, for instance, is impossible. But if you ask the right question maybe you can get an interesting answer.

As for the question of how long the human species will last Gott offers some wise words. When the author of the New Yorker article, Timothy Ferris, asked his friends how long humans would last, "most people predicted either that humans beings will last less than two hundred years or that we're good for more than ten million years." To which Gott responded, "That's because people like to think they're living in special times. We like to think of ourselves as near the beginning of things, or in an apocalyptic situation near the end. It's more dramatic that way. A lot of people might say, 'Oh, but we are in a special epoch. We're in the epoch when men first went to the moon, when we discovered genetic engineering, nuclear energy, and so forth.' My answer to this is that the Copernican principle predicts that you will be living in a high-population century—most people do, just as most people come from cities with higher than average populations, in larger than average nations. It's people who make discoveries, so if you live when there are more people around, you should expect to live in an age when a lot of interesting discoveries are being made."

19. Nassim Taleb: The Winner-Take-All Effect In Longevity

Nassim Taleb elaborates on the Copernican Principle, a concept first introduced on Farnham Street in How To Predict Everything.

For the perishable, every additional day in its life translates into a shorter additional life expectancy. For the nonperishable, every additional day implies a longer life expectancy. So the longer a technology lives, the longer it is expected to live. Let me illustrate the point. Say I have for sole information about a gentleman that he is 40 years old and I want to predict how long he will live. I can look at actuarial tables and find his age-adjusted life expectancy as used by insurance companies. The table will predict that he has an extra 44 to go. Next year, when he turns 41 (or, equivalently, if apply the reasoning today to another person currently 41), he will have a little more than 43 years to go. So every year that lapses reduces his life expectancy by about a year (actually, a little less than a year, so if his life expectancy at birth is 80, his life expectancy at 80 will not be zero, but another decade or so).

The opposite applies to nonperishable items. I am simplifying numbers here for clarity. If a book has been in print for forty years, I can expect it to be in print for another forty years. But, and that is the main difference, if it survives another decade, then it will be expected to be in print another fifty years. This, simply, as a rule, tells you why things that have been around for a long time are not “aging” like persons, but “aging” in reverse. Every year that passes without extinction doubles the additional life expectancy. This is an indicator of some robustness. The robustness of an item is proportional to its life!

This is the “winner-take-all” effect in longevity.

The main argument against this idea is the counterexample — newspapers and traditional telephone lines come to mind. These technologies, widely considered inefficient and dying, have been around for a long time. Yet the Copernican Principle would suggest they will continue to live on for a long time.

These arguments miss the point of probability. The argument is not about a specific example, but rather about the life expectancy, which is, Taleb writes “simply a probabilistically derived average.”

Perhaps an example, from Taleb, will help illustrate. If I were to ask you to guess the life expectancy of the average 40 year old man, you would probably guess around 80 (at least that's what the actuarial tables likely reveal). However, if I now add that the man is suffering from cancer, we would revisit our decision and most likely revise our estimate downward. “It would,” Taleb writes, “be a mistake to think that he has forty four more years to live, like others in his age group who are cancer-free.”

20. Economists Are Overconfident. So Are You.

The point of regression analysis is to make predictions based on past relationships. “My concern,” one of the authors of the paper said, “is that when reading economics journal articles you get the impression that the world is much more predictable than it is.”

What Soyer and Hogarth did was get 257 economists to read about a regression analysis that related independent variable X to dependent variable Y, then answer questions about the probabilities of various outcomes (example: if X is 1, what’s the probability of Y being greater than 0.936?).

When the results were presented in the way empirical results usually are presented in economics journals — as the average outcomes of the regression followed by a few error terms — the economists did a really bad job of answering the questions. They paid too much attention to the averages, and too little to the uncertainties inherent in them, thereby displaying too much confidence.

When the economists were shown the numerical results plus scatter graphs of the same data, they did slightly better. The economists who were shown only the graphs and none of the numerical results, meanwhile, actually got most of the answers right, or close to right. The bigger point here, which Soyer and Hogarth have elaborated in other research, is that we tend to understand probabilistic information much better when it’s presented in visual form than if we’re just shown the numbers. (This was also a key argument of Sam Savage’s edifying and entertaining 2009 book The Flaw of Averages.) What’s so interesting is to learn that statistically literate experts are just as likely to glom onto the point estimate and discount the uncertainty as, say, innumerate journalists reporting the results of political polls.

21. Daniel Kahneman — What I Know

Nobel prize-winning psychologist Daniel Kahneman talks with the Guardian about his pessimistic mother, the delusion of investment bankers and the need for irony.

Human beings cannot comprehend very large or very small numbers. It would be useful for us to acknowledge that fact.

My main work has concerned judgment and decision-making. But I never felt I was studying the stupidity of mankind in the third person. I always felt I was studying my own mistakes.

Happiness is complicated. There are two components. One is strongly genetic; the second is a question of how you feel at any moment. I am pretty content, but I had a very pessimistic mother, and I've always been known as a pessimist.

It was always assumed I would be a professor. I grew up thinking it.

There is a powerful idea that we should want to be richer. I went to a financial advisor in the States and said: "I don't really want to get richer, but I would like to continue to live like I do." She said: "I can't work with you."

Collaboration is not only more creative, it is more fun. Amos Tversky, my research partner, and I were better together than on our own. We sort of knew that. Mostly it was extremely pleasant not trying to work everything out yourself.

A sense of irony is essential. When we wrote our first paper, "The Law of Small Numbers", we were laughing all the time we wrote it. A colleague we showed it to said: "This is going to change things." I didn't take him seriously.

Many people now say they knew a financial crisis was coming, but they didn't really. After a crisis we tell ourselves we understand why it happened and maintain the illusion that the world is understandable. In fact, we should accept the world is incomprehensible much of the time.

Motives are rarely straightforward. When the war started my father was chief of research for a company that was part of L'Oréal in Paris. The owner of L'Oréal was also a main funder of the fascist party in France, and antisemitic. But he protected my [Jewish] father during the war when he was taken by the Nazis.

People who wouldn't even come to your funeral seem to take simple pleasure in the fact that you have won the Nobel prize [for economic sciences], and it makes them feel good about themselves to feel that way. For a while you are spreading joy.

Investment bankers believe in what they do. They don't want to hear that their decisions are no better than chance. The rest of us pay for their delusions.

Despite 45 years of work in the field, I am still inclined to make over-confident predictions.

Economists have a mystique among social scientists because they know mathematics. They are quite good at explaining what has happened after it has happened, but rarely before. I don't think of myself as an economist at all.

I enjoy being active but I look forward to the day when I can retire to the internet.

22. Simplicity's Best Friend: Small Groups of Smart People

More brains don't necessarily lead to better ideas. When it came to leading meetings, Steve Jobs had no qualms about tossing the least necessary person out of the room.

An excerpt from Insanely Simple: The Obsession That Drives Apple's Success:

One particular day, there appeared in our midst a woman from Apple with whom I was unfamiliar. I don't recall her name, as she never appeared in our world again, so for the purposes of this tale, I'll call her Lorrie. She took her seat with the rest of us as Steve breezed into the boardroom, right on time. Steve was in a sociable mood, so we chatted it up for a few minutes, and then the meeting began. "Before we start, let me just update you on a few things," said Steve, his eyes surveying the room. "First off, let's talk about iMac—" He stopped cold. His eyes locked on to the one thing in the room that didn't look right. Pointing to Lorrie, he said, "Who are you?"

Lorrie was a bit stunned to be called out like that, but she calmly explained that she'd been asked to attend because she was involved with some of the marketing projects we'd be discussing. Steve heard it. Processed it. Then he hit her with the Simple Stick. "I don't think we need you in this meeting, Lorrie. Thanks," he said. Then, as if that diversion had never occurred—and as if Lorrie never existed—he continued with his update. So, just as the meeting started, in front of eight or so people whom Steve did want to see at the table, poor Lorrie had to pack up her belongings, rise from her chair, and take the long walk across the room toward the door. Her crime: She had nothing to add.

Simplicity's Best Friend: Small Groups of Smart People

Start with small groups of smart people—and keep them small. Every time the body count goes higher, you're simply inviting complexity to take a seat at the table. The small-group principle is deeply woven into the religion of Simplicity. It's key to Apple's ongoing success and key to any organization that wants to nurture quality thinking. The idea is pretty basic: Everyone in the room should be there for a reason. There's no such thing as a "mercy invitation." Either you're critical to the meeting or you're not. It's nothing personal, just business.

Steve Jobs actively resisted any behavior he believed representative of the way big companies think—even though Apple had been a big company for many years. He knew that small groups composed of the smartest and most creative people had propelled Apple to its amazing success, and he had no intention of ever changing that. When he called a meeting or reported to a meeting, his expectation was that everyone in the room would be an essential participant. Spectators were not welcome.

This was based on the somewhat obvious idea that a smaller group would be more focused and motivated than a large group, and smarter people will do higher quality work. For a principle that would seem to be common sense, it's surprising how many organizations fail to observe it. How many overpopulated meetings do you sit through during the course of a year? How many of those meetings get sidetracked or lose focus in a way that would never occur if the group were half the size? The small-group rule requires enforcement, but it's worth the cost.

Remember, complexity normally offers the easy way out. It's easier to remain silent and let the Lorries of the world take their seats at the table, and most of us are too mannerly to perform a public ejection. But if you don't act to keep the group small, you're creating an exception to the rule—and Simplicity is never achieved through exceptions. Truthfully, you can do the brutal thing without being brutal. Just explain your reasons. Keep the group small.

Prior to working with Steve Jobs, I worked with a number of more traditional big companies. So it was a shock to my system (in a good way) when I entered Steve's world of Simplicity. In Apple's culture, progress was much easier to attain. It was also a shock to my system (in a bad way) when I left Steve's world and found myself suffering through the same old issues with more traditional organizations again.

And

Out in the real world, when I talk about small groups of smart people, I rarely get any pushback. That's because common sense tells us it's the right way to go. Most people know from experience that the fastest way to lose focus, squander valuable time, and water down great ideas is to entrust them to a larger group. Just as we know that there is equal danger in putting ideas at the mercy of a large group of approvers.

One reason why large, unwieldy groups tend to be created in many companies is that the culture of a company is bigger than any one person. It's hard to change "the way we do things here." This is where the zealots of Simplicity need to step in and overcome the inertia. One must be judicious and realistic about applying the small-group principle.

Simply making groups smaller will obviously not solve all problems, and "small" is a relative term. Only you know your business and the nature of your projects, so only you can draw the line between too few people and too many. You need to be the enforcer and be prepared to hit the process with the Simple Stick when the group is threatened with unnecessary expansion.

23. The Oracle, a Manual of the Art of Discretion

In The Art of Worldly Wisdom, Christopher Maurer translates this gem from Baltasar Gracián y Morales:

Know how to sell your wares, intrinsic quality isn't enough. Not everyone bites at substance or looks for inner value. People like to follow the crowd; they go someplace because they see other people do so. It takes much skill to explain something's value. You can use praise, for praise arouses desire. At other times you can give things a good name (but be sure to flee from affectation). Another trick is to offer something only to those in the know, for everyone believes himself an expert, and the person who isn't will want to be one. Never praise things for being easy or common: you'll make them seem vulgar and facile. Everybody goes for something unique. Uniqueness appeals both to the taste and to the intellect.

24. David Foster Wallace: The Paradox of Plagiarism

David Foster Wallace (1962–2008) remains one of the most revered authors of our time. His timeless collection of wisdom includes everything from his famous commencement speech This is Water to his profound thoughts on the relationship between ambition and perfectionism and writing in the age of information.

In The Pale King, published posthumously, Foster Wallace describes the paradox of plagiarism.

It was all pretty incredible. In many respects, this college was my introduction to the stark realities of class, economic stratification, and the very different financial realities that different sorts of Americans inhabited.

Some of these upper-class students were indeed spoiled, cretinous, and/or untroubled by questions of ethics. Others were under great family pressure and failing, for whatever reasons, to work up to what their parents considered their true grade potential. Some just didn't manage their time and responsibilities well, and found themselves up against the wall on an assignment. I'm sure you get the basic picture. Let's just say that, as a way of positioning myself to pay off some of my loans at an accelerated rate, I provided a certain service. This service was not cheap, but I was quite good at it, and careful. E.g., I always demanded a large enough sample of a client's prior writing to determine how he tended to think and sound, and I never made the mistake of delivering something that was unrealistically superior to someone's own previous work. You can probably also see why these sorts of exercises would be good apprentice training for someone interested in so-called 'creative writing.'

... To anticipate a likely question, let me concede that the ethics here were gray at best. This is why I chose to be honest, just above, about not being impoverished or needing the extra income in order to eat anything. I was not desperate. I was, though, trying to accumulate some savings against what I anticipated to be debilitating post-grad debt. I am aware that this is not an excuse in the strict sense, but I do believe it serves as at least an explanation; and there were also other, more general factors and contexts that might be seen as mitigating. For one, the college itself turned out to have a lot of moral hypocrisy about it, e.g., congratulating itself on its diversity and the leftist piety of its politics while in reality going about the business of preparing elite kids to enter elite professions and make a great deal of money, thus increasing the pool of prosperous alumni donors.

... The basic view I held was that, whereas there may have been elements of my enterprise that might technically qualify as aiding or abetting a client's decision to violate the college's Code of Academic Honesty; that decision, as well as the practical and moral responsibility for it rested with the client. I was undertaking certain freelance writing assignments for pay; why certain students wanted certain papers of a certain length on certain topics, and why they chose to do them with them after delivery, were not my business.

Suffice it to say that this view was not shared by the college's Judicial Board in late 1984. Here the story gets complex and a bit lurid, and a SOP memoir would probably linger on the details and the rank unfairness of hypocrisies involved.

The paradox of plagiarism

The paradox of plagiarism is that it actually requires a lot of care and hard work to pull off successfully, since the original text's style, substance, and logical sequences have to be modified enough so that the plagiarism isn't totally, insultingly obvious to the professor who's grading it.

Update: D.T. Max questions whether David Foster Wallace ever did the stuff he says he did in the Pale King.

Practically speaking, one of the great struggles was to figure out what really happened or at least get close to it. David was writing his autobiography even as he was living it and the life and the narrative coincided but were not identical. Take an example. David used to tell people he sold thesis help for pot or money at Amherst. He even has his doppel do it in

The Pale King and Stonecipher LaVache Beadsman, something of a stand-in for David, does it in The Broom of the System. David was one of the smartest people anyone ever met in their lives—everyone agrees on that—so it's obvious that in philosophy or English, and probably history or French or economics, all subjects he got A-pluses in—he could have done it. Anyone would have been smart to make that trade with him. But did it ever happen? His college roommate and confidante Mark Costello, the one who knew him best in those years, thinks not. He thinks it's David's self-mythologizing. I never found anyone on the receiving end of such a transaction or had direct knowledge of one, so it's not in the book. If I were writing a novel with David as the protagonist, it would certainly be something the character did. It's something he should have done if he didn't.

25. Insanely Simple

I learned quite a lot about organizational culture while reading Ken Segall's Insanely Simple: The Obsession That Drives Apple's Success.

Segall worked closely with Steve Jobs as an ad agency creative director for NeXT and Apple and was a member of the team that created the legendary 'Think Different' campaign. Oh, and he's also the guy responsible for the "i" that found itself in Apple product names like the iPad and iPhone.

Segall compares the difference between working *with* Apple and working with *other companies* like Dell and Intel and the contrast is shocking. Apple might be the biggest corporation in the world but it's certainly not the most bureaucratic.

Here are some of my highlights from the book.

Why is it that only a small handful of companies are able to produce truly great marketing campaigns?

One major reason is that most big organizations are simply awful at thinking small. They're unable to streamline complicated processes. Even when they successfully identify their challenges, develop strategies, and create great work that brings them to life, their processes choke the life out of that work. They inflict endless meetings and multiple approvals upon what should be a simpler way of working.

What you ask for and what you allow ...

Companies that don't have a leader with Steve's passion tend to see marketing in more clinical terms. For them, marketing is just another spoke in the wheel, an organization within the organization. Chief marketers in these companies typically demand brilliant creativity but support processes that make it difficult. They seem to think that if they demand greatness, it will somehow land on their desk.

If process is king ...

When process is king, ideas will never be. It takes only Common Sense to recognize that the more layers you add to a process, the more watered down the final work will become.

Most companies have an inability to focus ...

Many companies can't stop themselves from responding to every opportunity, trying to please every customer and close every sale — when in fact they would be better served by making their product lineup logical and easier to navigate. They seem to forget that trying to please everyone is a good way to please no one.

Powerpoint is a poor method of communication ...

It drove Steve batty to see in twenty slides what could be spoken in three sentences. He valued his time way too much for that. He preferred straight talk and raw content to a slick presentation. In fact, a slick presentation would only make him suspect that you were fluffing up the few facts you really had. It meant that you'd devoted valuable time to the wrapping of your idea rather than thinking through the content itself. ... Few people who attend an overblown, hard-to-digest presentation return to their offices eager to set the world on fire. Most prefer to head for the nearest bar. This is not the way to inspire people to greatness. This is simply checking off boxes to make sure every last fact is on the table. It serves the purpose of the presenters, but not the attendees.

Did Jobs listen to the experts?

This is not to say that Steve's skepticism led him to ignore his experts' advice. It just means that he would consider their advice in context of other evidence, his larger goals for the company, and common sense.

26. The Checklist Manifesto: How to Get Things Right

It's no secret that I'm a huge fan of Atul Gawande. A reader recently pointed out that I hadn't covered his most recent book, *The Checklist Manifesto: How to Get Things Right*. I had only covered an interesting subset of the book—why we fail.

The Checklist Manifesto

To put us in the proper context, we're smart. Not scary smart but smart enough. We have skills, and we generally put them in the most highly trained and hardworking people we can find. We have the most educated society in history. And we've accomplished a lot. Nevertheless, sometimes, success escapes us for avoidable reasons. Not only are these failures common—across everything from medicine to finance—but they are also frustrating. We should know better, but we don't. The reason we don't learn, Gawande argues, is evident:

the volume and complexity of what we know has exceeded our individual ability to deliver its benefits correctly, safely, or reliably. Knowledge has both saved us and burdened us.

To overcome this, we need a strategy. Something that “builds on experience and takes advantage of the knowledge people have but somehow also makes up for our inevitable human inadequacies.” We need a checklist.

In response to increasing complexity, we've become more specialized. We divide the problem up. It's not just the growing breadth and quantity of knowledge that makes things more complicated, although they certainly are significant contributors. It is also execution. In every field from medicine to construction, there are a slew of practical procedures, policies, and best practices. Gawande breaks this down for the modern medical case: *[Y]ou have a desperately sick patient and in order to have a chance of saving him you have to get the knowledge right and then you have to make sure that the 178 daily tasks that follow are done correctly—despite some monitor's alarm going off for God knows what reason, despite the patient in the next bed crashing, despite a nurse poking his head around the curtain to ask whether someone could help “get this lady's chest open.” There is complexity upon complexity. And even specialization has begun to seem inadequate. So what do you do?*

The response of the medical profession, like most others, is to move from specialization to super-specialization. Gawande argues that these super-specialists have two advantages over ordinary specialists: greater knowledge of the things that matter and “a learned ability to handle the complexities of that particular job.” But even for these super specialists, avoiding mistakes is proving impossible.

Modern professions, like medicine, with their dazzling successes and spectacular failures, pose a significant challenge: “What do you do when expertise is not enough? What do you do when even the super-specialists fail?”

The origins of the checklist.

On October 30, 1935, at Wright Air Field in Dayton, Ohio, the U.S. Army Air Corps held a competition for airplane manufacturers vying to build the next-generation of the long-range bomber. Only it wasn't supposed to be much of a competition at all. The Boeing Corporation's gleaming aluminum-alloy Model 299 was expected to steal the show, its design far superior to those of the competition. In other words, it was just a formality. As the Model 299 test plane taxied onto the runway, a small group of army brass and manufacturing executives watched. The plane took off without a hitch. Then suddenly, at about 300 feet, it stalled, turned on one wing, and crashed killing two of the five crew members, including the pilot Major Hill.

Of course, everyone wanted to know what had happened. An investigation revealed that there was nothing to indicate any problems mechanically with the plane. It was a “pilot error.” The problem with the new plane, if there was one, was that it was substantially more complex than the previous aircraft. Among other things, there were 4 engines, each with its own fuel-mix, wing flaps, trim that needed constant adjustment, and propellers

requiring pitch adjustment. While trying to keep up with the increased complexity, Hill had forgotten to release a new locking mechanism on the rudder controls. The new plane was too much for anyone to fly. The unexpected winner was the smaller designed Douglas. Here is where it really gets interesting. The army, convinced of the technical superiority of the plane, ordered a few anyway. If you're thinking they'd just put the pilots through more training to fly the plane, you'd be wrong. Major Hill, the chief of flight testing, was an experienced pilot, so longer training was unlikely to result in improvement. Instead, they created a pilot's checklist.

The pilots made the list simple and short. It fit on an index card with step-by-step instructions for takeoff, flying, landing, and taxiing. It was as if someone all of a sudden gave an experienced automobile driver a checklist of things that would be obvious to them. There was nothing on the checklist they didn't know. Stuff like, check that the instruments are set, the door closed. Basics. That checklist changed the course of history and quite possibly the war. The pilots went on to fly the Model 299 a "total of 1.8 million miles" without a single accident and as a result the army ordered over 13,000 of them. In *The Checklist Manifesto*, Gawande argues that most of today's work has entered a checklist phase.

Substantial parts of what software designers, financial managers, firefighters, police officers, lawyers, and most certainly clinicians do are now too complex for them to carry out reliably from memory alone.

Yet, no one wants to use a checklist. We believe "our jobs are too complicated to reduce to a checklist." After all, we don't work at McDonald's, right?

In a complex environment, experts are up against two main difficulties. The first is the fallibility of human memory and attention, especially when it comes to mundane, routine matters that are easily overlooked under the strain of more pressing events. (When you've got a patient throwing up and an upset family member asking you what's going on, it can be easy to forget that you have not checked her pulse.) Faulty memory and distraction are a particular danger in what engineers call all-or-none processes: whether running to the store to buy ingredients for a cake, preparing an airplane for takeoff, or evaluating a sick person in the hospital, if you miss just one key thing, you might as well not have made the effort at all.

A further difficulty, just as insidious, is that people can lull themselves into skipping steps even when they remember them. In complex processes, after all, certain steps don't always matter. ... "This has never been a problem before," people say. Until one day it is. Checklists seem to provide protection against such failures. They remind us of the minimum necessary steps and make them explicit. They not only offer the possibility of verification but also instill a kind of discipline of higher performance.

In news that would shock bureaucracies and governments alike, the strategy a lot of industries use to get things right in complex environments is to give employees power. Most authorities, in response to risk, tend to centralize power and decision making. Sometimes that's even the point of a checklist—to make sure the people below you are doing things in the manner in which you want. These checklists, the McDonald's type checklists, spell out the tiniest detail of every critical step. These serve their purpose, but they also create a group of employees no longer able to adapt. When things change, as they always do, you're now faced with a non-routine problem. "The philosophy," writes Gawande, "is that you push the power of decision making out to the periphery and away from the center. You give people the room to adapt, based on their experience and expertise. All you ask is that they talk to one another and take responsibility. That is what works."

...the real lesson is that under conditions of true complexity—where the knowledge required exceeds that of any individual and unpredictability reigns—efforts to dictate every step from the center will fail. People need room to act and adapt. Yet they cannot succeed

as isolated individuals, either—that is anarchy. Instead, they require a seemingly contradictory mix of freedom and expectation—expectation to coordinate, for example, and also to measure progress toward common goals.

This was the understanding people in the skyscraper-building industry had grasped. More remarkably, they had learned to codify that understanding into simple checklists. They had made the reliable management of complexity a routine.

That routine requires balancing a number of virtues: freedom and discipline, craft and protocol, specialized ability and group collaboration. And for checklists to help achieve that balance, they have to take two almost opposing forms. They supply a set of checks to ensure the stupid but critical stuff is not overlooked, and they supply another set of checks to ensure people talk and coordinate and accept responsibility while nonetheless being left the power to manage the nuances and unpredictabilities the best they know how.

I came away from Katrina and the builders with a kind of theory: under conditions of complexity, not only are checklists a help, they are required for success. There must always be room for judgment, but judgment aided—and even enhanced—by procedure.

27. Alignment: The Key to Success Nobody Ever Taught You

I spend a lot of time thinking about this simple idea: The person who aligns themselves with the general principles of the world goes further and faster than the person who doesn't.

What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson.

— Joseph Tussman

The way to align yourself with the world is to take simple ideas seriously.

Consider compounding.

We know that spending less than we make, investing the difference in index funds, and waiting for a long time creates financial independence. Yet how many people follow this principle? Not many. Most of us know what works but fail to align ourselves with it.

Compounding applies to relationships too. Not just with your partner, but with your colleagues, friends, and even your customers. For relationships to compound, they must be win-win. But how many people take a consistent win-win approach? Not many. Again, we know what works, but fail to align ourselves with it.

Outcome over Ego

Here's the trick to seeing things differently: put your energy into *being* right, not *feeling* right. While that sounds simple, it's far from easy.

If you want to be right, you have to change your mind. When the evidence indicates the approach isn't working, change the approach. This is easy with something like math, where the answers are black and white, but harder with more subjective things.

Often the hardest things to change our minds about are the things that require us to understand that just because we can't see the results immediately doesn't mean they are not moving us closer or further from the outcome we want. For instance, eating a full pizza once won't make you unhealthy, but repeating that choice daily for years certainly will.

Feeling right, on the other hand, often requires you to believe you are an exception. You know the path to financial independence, but that takes too long. It's boring. Instead, you'd rather try the latest incarnation of a get-rich-quicker scheme that promises the outcome sooner. When it inevitably fails to produce the desired results, rather than tell yourself you made a mistake you chalk it up to the world not working as it should. It's as if that little voice in your head says, "You're not wrong; the world is."

Most of us would rather bargain with how the world works than accept how it does work, cooperate with it, and move forward. This happens in a lot of areas of life. Consider the general concept of health.

A lot of people think they don't have to take care of their health. They get too little sleep. They drink too much. They eat incredible amounts of processed food. They get little to no exercise. While they know health is important, at some level they think they are the exception. Acceptance is knowing you must care for your health because it is the foundation for everything else. Without health, everything else multiplies by zero.

We are tempted to believe we're the exception because it's the easy path.

Aligning with the world often requires you to pre-pay now for a result later. A little bit of pain today for gain tomorrow. And we don't like the sounds of that.

However, if you can align yourself with the world despite what those around you do, you'll quickly discover that it tends to do most of the work for you. It just won't take the first step for you. You have to take that one for yourself.

28. They Work Long Hours, but What About Results?

Robert Pozen writes an interesting piece in the New York Times on what happens when you value busyness over achievement.

It's 5 p.m. at the office. Working fast, you've finished your tasks for the day and want to go home. But none of your colleagues have left yet, so you stay another hour or two, surfing the Web and reading your e-mails again, so you don't come off as a slacker.

We've all been there right? He continues:

a measurement system based on hours makes no sense for knowledge workers. Their contribution should be measured by the value they create through applying their ideas and skills.

By applying an industrial-age mind-set to 21st-century professionals, many organizations are undermining incentives for workers to be efficient. If employees need to stay late in order to curry favor with the boss, what motivation do they have to get work done during normal business hours? After all, they can put in the requisite "face time" whether they are surfing the Internet or analyzing customer data. It's no surprise, then, that so many professionals find it easy to procrastinate and hard to stay on a task.

Busyness, however, is no substitute for achievement. When you work in an organization that values "busyness" things will only get busier. Before you know it you're coming earlier and staying later but you're not actually doing more work — you're doing less.

29. None of us really likes honesty

None of us really likes honesty. We prefer deception—but only when it is unabashedly flattering or artfully camouflaged. Groups seem to need to believe that they are superior to others and that they have a purpose greater than just passing along their genes to the next generation. Individuals seem to need similar delusions—about who they are and why they do what they do. They need heroes, however fraudulent. People ask actors who play doctors on television what they should do for their ailments, although they know perfectly well that the actors are just playing a role. Studies show that people are more likely to accept the opinion of a confident con man than the cautious view of someone who actually knows what he is talking about. And professionals who form overconfident opinions on the basis of incorrect readings of the facts are more likely to succeed than their more competent peers who display greater doubt.

What's more, deception works best, according to studies by psychologists, when the person doing the deceiving is fool enough to be deceived, too; that is, when he believes his own lies. That is why incompetent leaders—who are naive enough to fall for their own guff—are such a danger to civilized life. If they are modern leaders, they must delude themselves into thinking they know how to make the world a better place.

— Mobs, Messiahs, and Markets: Surviving the Public Spectacle in Finance and Politics

Further in the book, Bonner writes:

Like all world improvers, Che (Guevara) claimed a remarkable ability to look into the future and then improve it before it happened. Of course, we all try to peek ahead and try to avoid traffic collisions and bad restaurants, but only a chump thinks he knows best how to improve the entire planet.

30. The Human Mind has a Shut-Off Device

Once you've formed a belief, adding exceptions and justifications becomes easier than updating it.

Ryan Holiday writes about this in *Trust Me, I'm Lying*:

Once the mind has accepted a plausible explanation for something, it becomes a framework for all the information that is perceived after it. We're drawn, subconsciously, to fit and contort all the subsequent knowledge we receive into our framework, whether it fits or not. Psychologists call this "cognitive rigidity". The facts that built an original premise are gone, but the conclusion remains—the general feeling of our opinion floats over the collapsed foundation that established it.

Information overload, "busyness," speed, and emotion all exacerbate this phenomenon. They make it even harder to update our beliefs or remain open-minded.

Charlie Munger said something similar:

[W]hat I'm saying here is that the human mind is a lot like the human egg, and the human egg has a shut-off device. When one sperm gets in, it shuts down so the next one can't get in. The human mind has a big tendency of the same sort. And here again, it doesn't just catch ordinary mortals; it catches the deans of physics. According to Max Planck, the really innovative, important new physics was never really accepted by the old guard. Instead a new guard came along that was less brain-blocked by its previous conclusions. And if Max Planck's crowd had this consistency and commitment tendency that kept their old inclusions intact in spite of disconfirming evidence, you can imagine what the crowd that you and I are part of behaves like.

Once a belief is formed, the mind tends to stick to it, making it difficult to accept new ideas. Even the most intelligent people can be trapped by their previous conclusions, so it's important to stay open-minded and avoid being influenced solely by popular opinion. The trick, if there is one, is to form working beliefs, not permanent beliefs.

31. Trust Me, I'm Lying: Why Sites Like Gawker Manipulate You

"A newspaper is a business out to make money through advertising revenue. That is predicated on its circulation and you know what the circulation depends on. ..."
— *The Long Goodbye*, Raymond Chandler

Ryan Holiday's book Trust Me, I'm Lying: Confessions of a Media Manipulator, offers a penetrating look at the incentives of media.

Holiday, himself, is a practitioner of the dark arts of media manipulation and uses these techniques to make a living.

"Usually, it is a simple hustle," Holiday writes. "Someone pays me, I manufacture a story for them, and we trade it up the chain — from a tiny blog to Gawker to a website of a local news network to the Huffington Post to the major newspapers to cable news and back again, until the unreal becomes real. Sometimes I start by planting a story. Sometimes I put out a press release or ask a friend to break a story on their blog. Sometimes I 'leak' a document. Sometimes I fabricate a document and leak that. Really, it can be anything, from vandalizing a Wikipedia page to producing an expensive viral video. However the play starts, the end is the same: The economics of the Internet are exploited to change public perception — and sell product."

For me, the most interesting part of the book was the history of the press, which begins with the Party Press, moves on to the Yellow Press and ends with the Modern Press (aka Subscription Press). Holiday gives us this history lesson to explain how news outlets sold their product over the years.

The Party Press

The earliest forms of newspapers were a function of political parties. These were media outlets for party leaders to speak to party members, to give them the information they needed and wanted. ... These papers were not some early version of Fox News. They usually were one-man shops. The editor-publisher-writer-printer was the dedicated steward of a very valuable service to that party in his town. The service was the ability to communicate ideas and information about important issues. ...

This first stage of journalism was limited in its scope and impact. Because of the size and nature of its audience, the party press was not in the news business. They were in the editorial business. It was a different time and style, one that would be eclipsed by changes in technology and distribution.

The Yellow Press

Newspapers changed the moment that Benjamin Day launched the New York Sun in 1833. It was not so much his paper that changed everything but his way of selling it: on the street, one copy at a time. He hired the unemployed to hawk his papers and immediately solved a major problem that had plagued the party presses: unpaid subscriptions. Day's "cash and carry" method offered no credit. You bought and walked. The Sun, with this simple innovation in distribution, invented the news and the newspaper. A thousand imitators followed.

These papers weren't delivered to your doorstep. They had to be exciting and loud enough to fight for their sales on street corners, in barrooms, and at train stations. Because of the change in distribution methods and the increased speed of the printing press, newspapers truly became newspapers. Their sole aim was to get new information, get it to print faster, get it more exclusively than their competition. It meant the decline of the editorial. These papers relied on gossip. ...

... He (James Gordon Bennett) knew that the newspaper's role was "not to instruct but to startle." His paper was anti-black, anti-immigrant, and anti-subtlety. These causes sold papers—to both people who loved them for it and people who hated them for it. And they bought and they bought.

... The need to sell every issue anew each day creates a challenge I call the “One-Off Problem.” Bennett’s papers solved it by getting attention however they could.

The first issue of Bennett’s Herald looked like this: First page—eye-catching but quickly digestible miscellany; Second page—the heart of the paper, editorial and news; Third page—local; Fourth page—advertising and filler. There was something for everyone. It was short, zesty. He later tried to emphasize quality editorial instead of disposable news by swapping the first two pages. The results were disastrous. He couldn’t sell papers on the street that way.

The One-Off Problem shaped more than just the design and layout of the newspaper. When news is sold on a one-off basis, publishers can’t sit back and let the news come to them. There isn’t enough of it, and what comes naturally isn’t exciting enough. So they must create the news that will sell their papers. When reporters were sent out to cover spectacles and events, they knew that their job was to cover the news when it was there and to make it up when it was not.

Speaking of the markers of “yellow journalism” (the One-Off problem), author of Yellow Journalism and media historian W.J. Campbell wrote:

As practiced more than 100 years ago, yellow journalism was a robust, enterprising genre characterized by these practices and features:

- the frequent use of multicolumn headlines that sometimes stretched across the front page.*
- a variety of topics reported on the front page, including news of politics, war, international diplomacy, sports, and society.*
- the generous and imaginative use of illustrations, including photographs and other graphic representations such as locator maps.*
- bold and experimental layouts, including those in which one report and illustration would dominate the front page. Such layouts sometimes were enhanced by the use of color.*
- a tendency to rely on anonymous sources, particularly in dispatches of leading correspondents.*
- a penchant for self-promotion, to call attention eagerly to the paper’s accomplishments. This tendency was notably evident in crusades against monopolies and municipal corruption.*

As defined above and as practiced more than a century ago, yellow journalism could not be called predictable, boring, or uninspired — complaints of the sort that are not infrequently raised about U.S. newspapers in the early twenty-first century.

Does any of that sound familiar? It should. Just take a look at Gawker and The Huffington Post. It’s the modern version of the One-Off problem. Instead of trying to sell you a copy of the newspaper by shouting on the street corner, today’s media want page views. In yellow journalism, headlines and promotions were more important than content.

So what happened after the yellow press? Holiday continues:

The Modern Stable Press

... Adolph S. Ochs, publisher of the New York Times, ushered in the next iteration of news. Ochs, like most great businessmen, understood that doing things differently was the way to great wealth. In the case of his newly acquired newspaper and the dirty, broken world of yellow journalism, he made the pronouncement that “decency meant dollars.”

He immediately set out to change the conditions that allowed the Bennett, Hearst, Pulitzer, and their imitators to flourish. He was the first publisher to solicit subscriptions via

telephone. He offered contests to his salesman. He gave them quotas and goals for the number of subscribers they were expected to bring in.

He understood that people bought the yellow papers because they were cheap—and they didn't have any other options. He felt that if they had a choice, they'd pick something better. He intended to be that option. First, he would match his competitors' prices, and then he would deliver a paper that far surpassed the value implied by the low price.

It worked. When he dropped the price of the *Times* to one cent, circulation tripled in the first year. He would compete on content. He came up with the phrase "All the News That's Fit to Print" as a mission statement for the editorial staff, two months after taking over the paper. The less known runner-up says almost as much: "All the World's News, But Not a School for Scandal."

Of course, the transition to the modern press wasn't immediate. The subscription model, however, better aligned the incentives of the reader and newspaperman. Subscriptions change everything because readers who are misled unsubscribe. Content, not headlines, ruled the day.

"With Ochs's move," Holiday writes, "reputation began to matter more than notoriety. This was the era of the professionalization of journalism. For the first time, it created a sense of obligation, not just to the paper and circulation, but also to the audience."

While subscription journalism meant you didn't have to peddle papers on the street, that didn't make it a perfect system.

As the character Philip Marlowe observed in Raymond Chandler's novel The Long Goodbye:

Newspapers are owned and published by rich men. Rich men all belong to the same club. Sure, there's competition—hard tough competition for circulation, for newsbeats, for exclusive stories. Just so long as it doesn't damage the prestige and privilege and position of the owners.

We've had a good run. For a long time journalism was primarily sold via subscriptions (the stable press model) but now we're moving quickly towards online à la Carte offerings.

Journalism is no longer selling a package. Now each story is like a mini paper on the side of the street corner in the 1840's trying to be heard over all of the other stories.

Eli Pariser wrote in The Filter Bubble:

Our bodies are programmed to consume fat and sugars because they're rare in nature. Thus, when they come around, we should grab them. In the same way, we're biologically programmed to be attentive to things that stimulate: content that is gross, violent, or sexual and that gossip which is humiliating, embarrassing, or offensive. If we're not careful, we're going to develop the psychological equivalent of obesity. We'll find ourselves consuming content that is least beneficial for ourselves or society as a whole.

... Each article ascends the most-forwarded lists or dies an ignominious death on its own.... The attention economy is ripping the binding, and the pages that get read are the pages that are frequently the most topical, scandalous, and viral.

Think about how you consume media today. You don't read one newspaper or blog. You read an assortment of many newspapers and blogs. And you don't pay for any of it. The trust relationship is fractured. Competition centers around who can create the most read story. That means journalism becomes about what spreads – not what's good.

MIT Media Studies Professor Henry Jenkins gives publishers and companies the following advice: "if it doesn't spread, it's dead." Spreading is traffic. Traffic is money.

So what spreads?

Joseph Campbell and Katherine Milkman, of the Wharton School looked into over 7,000 articles that made it on to the New York Times Most Emailed List. They conclude:

Virality is partially driven by physiological arousal. Content that evokes high-arousal positive (awe) or negative (anger or anxiety) emotions is more viral. Content that evokes low-arousal, or deactivating, emotions (e.g., sadness) is less viral.

Basically, virality is determined by how much anger the article causes. Not all extreme emotions spread. Sadness doesn't spread. Anger spreads. If anger spreads and financial incentives are somehow aligned to 'page views' more of our journalism will move towards what spreads.

Something analogous to Gresham's Law can be found in the One-Off problem. If each story has to find its own audience (i.e., it's no longer sold as a bundle) and compensation is derived from page views, we can expect incentives to favor a lot of low-cost articles with catchy headlines. In the end, we're likely to get the stories we want to read — not the ones we should read. If not part of subscription, we'll likely lose the in-depth reporting we've come to expect from some of the old media guards.

(side-note: I found the first part of Holiday's book — where he explains how page view media works and how he manipulated the system — pretty good. The book is not without it's "controversy" though. Overall it's a great read for anyone interested in the economics of new media.)

(update: a previous version of this post (ironically) sourced a site that accused Holiday of mis-quoting a study. Holiday contacted me and it appears that he used an older version of the study, which did, in fact, contain the quote he referenced in his book. The other site was wrong and my verification process was lax. My bad.)

*"If you're not paying for something,
you're not the customer; you're the product being sold."*

— Andrew Lewis

32. Jeff Bezos on Why People that Are Often Right Change Their Minds Often

Jeff Bezos recently stopped by the office of 37 Signals. After talking product strategy he answered some questions.

In his answer to one question he shared some thoughts on people who were "right a lot." *He said people who were right a lot of the time were people who often changed their minds. He doesn't think consistency of thought is a particularly positive trait. It's perfectly healthy — encouraged, even — to have an idea tomorrow that contradicted your idea today.*

He's observed that the smartest people are constantly revising their understanding, reconsidering a problem they thought they'd already solved. They're open to new points of view, new information, new ideas, contradictions, and challenges to their own way of thinking.

This doesn't mean you shouldn't have a well formed point of view, but it means you should consider your point of view as temporary.

What trait signified someone who was wrong a lot of the time? Someone obsessed with details that only support one point of view. If someone can't climb out of the details, and see the bigger picture from multiple angles, they're often wrong most of the time.

Bezos isn't alone. Warren Buffett's long time business partner Charlie Munger captures this:

If Berkshire has made modest progress, a good deal of it is because Warren and I are very good at destroying our own best-loved ideas. Any year that you don't destroy one of your best-loved ideas is probably a wasted year.

John Kenneth Galbraith put it this way:

Faced with the choice between changing one's mind and proving there is no need to do so, almost everyone gets busy on the proof.

33. Charlie Munger: Bad Morals Drive Out The Good

Charlie Munger on applying Gresham's Law to lending.

The idiotic ideas are all from the social science department and I would put economics in the social sciences department although it has some tinges of reality that remind you of arts and science.

In economics textbooks they teach you Gresham's Law: Bad money drives out good. But we don't have any bad money that amounts to anything. We don't have any coins that are worth a lot, that have precious metals that you can melt down. Nobody cares what the melt-down value of the quarter is in relationship to the dime, so Gresham's Law is a non-starter in the modern world. Bad money drives out good. But the new form of Gresham's Law is ungodly important.

The new form of Gresham's Law is brought into play – in economic thought, anyway – in the savings and loans crisis, when it was perfectly obvious that bad lending drives out good. Think of how powerful that model is. Think of the disaster that it creates for everybody.

You sit there in your little institution. All of the builders [are not good credits anymore], and you are in the business of lending money to builders. Unless you do the same idiotic thing [as] Joe Blow is doing down the street. Pete Johnson up the street wants to do something a little dumber and the thing just goes to a mighty tide. You've got to shrink the business that you love and maybe lay off the employees who have trusted you their careers and so forth or [make] a lot of dumb loans. At Berkshire Hathaway we try and let the place shrink. We never fire anybody, we tell them to go out and play golf. We sure as hell don't want to make any dumb loans. But that is very hard to do if you sit in a leadership position in society with people you helped recruit, you meet their wives and children and so forth. The bad loans drive out the good.

It isn't just bad loans. Bad morals drive out the good. If you want to run a check-cashing agency in [a] downtown big city, more than 100 percent of all the profit you could possibly earn can only be earned by flim-flamming people on the finance contracts. So if you aren't willing to cheat people – basically minorities – more than 100 percent of the profit can't be earned. Well, if you inherited the business or your idiot son-in-law is in it, you don't know what else to do. This is what I would call an adult problem and most people solve it in the adult fashion: They learn to tolerate the cheating. But that is not the right answer to people who want to live a larger and better life. But it is a form of Gresham's Law, the new Gresham's Law. One that is not taught in economics courses and should be. It is a really serious problem and, of course, it relates deeply to what happened to create the economic crisis. All kinds of people who you would be glad to have marry into your family compared to what you are otherwise going to get did things that were very regrettable under these pressures from the new Gresham's Law.

34. Ignorance Increases the Further Away you Are

While I'm not sure of the math, I enjoyed this quote from Mobs, Messiahs, and Markets: Surviving the Public Spectacle in Finance and Politics:

Ignorance increases the square of the distance from a given event, so the odds that things won't work out the way you expect must be multiplied by the squares of all the intervening events.

It reminded me of what Peter Bevelin Wrote in Seeking Wisdom:

The more independent steps that are involved in achieving a scenarios, the more opportunities for failure and the less likely it is that the scenario will happen. We often underestimate the number of steps, people, and decisions involved.

Add to this that we often forget that the reliability of a system is a function of the whole system. The weakest link sets the upper limit for the whole chain.

35. The Principle of Incomplete Knowledge

"All models are wrong, but some are useful"

— George Box

If you think of the complicated world we live in you quickly realize that we need to sort the inessential from the essential and then reduce complexity into something simpler. In the same way the map is not the territory, knowledge is only but a subset of what it represents. In why knowledge is incomplete, the authors elaborate on these ideas:

This principle can be deduced from a lot of other, more specific principles: Heisenberg's uncertainty principle, implying that the information a control system can get is necessarily incomplete; the relativistic principle of the finiteness of the speed of light, implying that the moment information arrives, it is already obsolete to some extent; the principle of bounded rationality, stating that a decision-maker in a real-world situation will never have all information necessary for making an optimal decision; the principle of the partiality of self-reference, a generalization of Gödel's incompleteness theorem, implying that a system cannot represent itself completely, and hence cannot have complete knowledge of how its own actions may feed back into the perturbations. As a more general argument, one might note that models must be simpler than the phenomena they are supposed to model. Otherwise, variation and selection processes would take as much time in the model as in the real world, and no anticipation would be possible, precluding any control. Finally, models are constructed by blind variation processes, and, hence, cannot be expected to reach any form of complete representation of an infinitely complex environment.

36. The Peter Principle

Laurence J. Peter and James Hull defined The Peter Principle: “In a hierarchically structured administration, people tend to be promoted up to their level of incompetence.” I think that’s fairly well understood, but what does it look like if we frame it in an evolutionary perspective?

The evolutionary generalization of the principle is less pessimistic in its implications, since evolution lacks the bureaucratic inertia that pushes and maintains people in an unfit position. But what will certainly remain is that systems confronted by evolutionary problems will quickly tackle the easy ones, but tend to get stuck in the difficult ones. The better (more fit, smarter, more competent, more adaptive) a system is, the more quickly it will solve all the easy problems, but the more difficult the problem will be it finally gets stuck in. Getting stuck here does not mean “being unfit”, it just means having reached the limit of one’s competence, and thus having great difficulty advancing further. This explains why even the most complex and adaptive species (such as ourselves, humans) are always still “struggling for survival” in their niches as energetically as are the most primitive organisms such as bacteria. If ever a species would get control over all its evolutionary problems, then the “Red Queen Principle” would make sure that new, more complex problems would arise, so that the species would continue to balance on the border of its domain of incompetence. In conclusion, the generalized Peter principle states that in evolution systems tend to develop up to the limit of their adaptive competence.

37. The Future Is Not Like The Past

From Everything Is Obvious: How Common Sense Fails Us:

The ubiquity of complex systems in the social world is important because it severely restricts the kinds of predictions we can make. In simple systems, that is, it is possible to predict with high probability what will actually happen—for example when Halley’s Comet will next return or what orbit a particular satellite will enter. For complex systems, by contrast, the best that we can hope for is to correctly predict the probability that something will happen. At first glance, these two exercises sound similar, but they’re fundamentally different. To see how, imagine that you’re calling the toss of a coin. Because it’s a random event, the best you can do is predict that it will come up heads, on average, half of the time. A rule that says “over the long run, 50% of coin tosses will be heads, and 50% will be tails” is, in fact, perfectly accurate in the sense that heads and tails do, on average, show up exactly half the time. But even knowing this rule, we still can’t predict the outcome of a single coin toss any more than 50% of the time, no matter what strategy we adopt. Complex systems are not really random in the same way that a coin toss is random, but in practice it’s extremely difficult to tell the difference.

38. Why Catastrophes Happen

From Ubiquity: Why Catastrophes Happen

There are many subtleties and twists in the story ... but the basic message, roughly speaking, is simple: The peculiar and exceptionally unstable organization of the critical state does indeed seem to be ubiquitous in our world. Researchers in the past few years have found its mathematical fingerprints in the workings of all the upheavals I've mentioned so far [earthquakes, eco-disasters, market crashes], as well as in the spreading of epidemics, the flaring of traffic jams, the patterns by which instructions trickle down from managers to workers in the office, and in many other things. At the heart of our story, then, lies the discovery that networks of things of all kinds – atoms, molecules, species, people, and even ideas – have a marked tendency to organize themselves along similar lines. On the basis of this insight, scientists are finally beginning to fathom what lies behind tumultuous events of all sorts, and to see patterns at work where they have never seen them before.

And

In this simplified setting of the sandpile, the power law also points to something else: the surprising conclusion that even the greatest of events have no special or exceptional causes. After all, every avalanche large or small starts out the same way, when a single grain falls and makes the pile just slightly too steep at one point. What makes one avalanche much larger than another has nothing to do with its original cause, and nothing to do with some special situation in the pile just before it starts. Rather, it has to do with the perpetually unstable organization of the critical state, which makes it always possible for the next grain to trigger an avalanche of any size.

To this, John Mauldin adds:

Now, let's couple this idea with a few other concepts. First, Hyman Minsky (who should have been a Nobel laureate) points out that stability leads to instability. The more comfortable we get with a given condition or trend, the longer it will persist and then when the trend fails, the more dramatic the correction. The problem with long term macroeconomic stability is that it tends to produce unstable financial arrangements. If we believe that tomorrow and next year will be the same as last week and last year, we are more willing to add debt or postpone savings in favor of current consumption. Thus, says Minsky, the longer the period of stability, the higher the potential risk for even greater instability when market participants must change their behavior.

Relating this to our sandpile, the longer that a critical state builds up in an economy, or in other words, the more "fingers of instability" that are allowed to develop a connection to other fingers of instability, the greater the potential for a serious "avalanche."

Couple this with Didier Sornette, in Why Stock Markets Crash (incidentally, this is a book Nassim Taleb recommends — "I learned more from this book than any other on disequilibrium.")

[T]he specific manner by which prices collapsed is not the most important problem: a crash occurs because the market has entered an unstable phase and any small disturbance or process may have triggered the instability. Think of a ruler held up vertically on your finger: this very unstable position will lead eventually to its collapse, as a result of a small (or an absence of adequate) motion of your hand or due to any tiny whiff of air. The collapse is fundamentally due to the unstable position; the instantaneous cause of the collapse is secondary.

Mauldin continues:

When things are unstable, it isn't the last grain of sand that causes the pile to collapse or the slight breeze that causes the ruler on your fingertip to fall. Those are the "proximate" causes. They're the closest reasons at hand for the collapse. The real reason, though, is the "remote" cause, the farthest reason. The farthest reason is the underlying instability of the system itself.

A fundamentally unstable system is exactly what we saw in the recent credit crisis. Consumers all through the world's largest economies borrowed money for all sorts of things, because times were good. Home prices would always go up and the stock market was back to its old trick of making 15% a year. And borrowing money was relatively cheap. You could get 2% short-term loans on homes, which seemingly rose in value 15% a year, so why not buy now and sell a few years down the road? Greed took over. Those risky loans were sold to investors by the tens and hundreds of billions of dollars, all over the world. And as with all debt sandpiles, the fault lines started to appear. Maybe it was that one loan in Las Vegas that was the critical piece of sand; we don't know, but the avalanche was triggered.

39. The Problem With Information

Nassim Taleb in Fooled by Randomness: The Hidden Role of Chance in Life and in the Markets:

The argument in favor of “new things” and even more “new new things” goes as follows: Look at the dramatic changes that have been brought about by the arrival of new technologies, such as the automobile, the airplane, the telephone, and the personal computer. Middlebrow inference (inference stripped of probabilistic thinking) would lead one to believe that all new technologies and inventions would likewise revolutionize our lives. But the answer is not so obvious: Here we only see and count the winners, to the exclusion of the losers (it is like saying that actors and writers are rich, ignoring the fact that actors are largely waiters — and lucky to be ones, for the less comely writers usually serve French fries at McDonald’s). Losers? The Saturday newspaper lists dozens of new patents of such items that can revolutionize our lives. People tend to infer that because some inventions have revolutionized our lives that inventions are good to endorse and we should favor the new over the old. I hold the opposite view. The opportunity cost of missing a “new new thing” like the airplane and the automobile is minuscule compared to the toxicity of all the garbage one has to go through to get to these jewels (assuming these have brought some improvement to our lives, which I frequently doubt).

Now the exact same argument applies to information. The problem with information is not that it is diverting and generally useless, but that it is toxic. We will examine the dubious value of the highly frequent news with a more technical discussion of signal filtering and observation frequency farther down. I will say here that such respect for the time-honored provides arguments to rule out any commerce with the babbling modern journalist and implies a minimal exposure to the media as a guiding principle for someone involved in decision making under uncertainty. If there is anything better than noise in the mass of “urgent” news pounding us, it would be like a needle in a haystack. People do not realize that the media is paid to get your attention. (For a detailed explanation on this see Trust Me, I’m Lying) For a journalist, silence rarely surpassed any word.

On the rare occasions when I boarded the 6:42 train to New York I observed with amazement the hordes of depressed business commuters (who seemed to prefer to be elsewhere) studiously buried in The Wall Street Journal, apprised of the minutiae of companies that, at the time of writing now, are probably out of business. Indeed it is difficult to ascertain whether they seem depressed because they are reading the newspaper, or if depressive people tend to read the newspaper, or if people who are living outside their genetic habitat both read the newspaper and look sleepy and depressed. But while early on in my career such focus on noise would have offended me intellectually, as I would have deemed such information as too statistically insignificant for the derivation of any meaningful conclusion, I currently look at it with delight. I am happy to see such mass-scale idiotic decision making, prone to overreaction in their post-perusal investment orders — in other words I currently see in the fact that people read such material an insurance for my continuing in the entertaining business of option trading against the fools of randomness. (It takes a huge investment in introspection to learn that the thirty or more hours spent “studying” the news last month neither had any predictive ability during your activities of that month nor did it impact your current knowledge of the world. This problem is similar to the weaknesses in our ability to correct for past errors: like a health club membership taken out to satisfy a New Year’s resolution, people often think that it will surely be the next match of news that will really make a difference to their understanding of things.)

40. The Worst Mistake of All: Outshining the Master

“Being defeated is hateful, and besting one’s boss is either foolish or fatal. Most people do not mind being surpassed in good fortune, character, or temperament, but no one, especially not a sovereign, likes to be surpassed in intelligence.”

— Baltasar Gracián

In *The 48 Laws of Power*, Robert Greene echoes the sentiments of Gracián’s quote above in the first law: Never Outshine the Master.

Greene writes:

Always make those above you feel comfortably superior. In your desire to please or impress them, do not go too far in displaying your talents or you might accomplish the opposite – inspire fear and insecurity. Make your masters appear more brilliant than they are and you will attain the heights of power.

Outshining the master is the worst mistake of all ...

Everyone has insecurities. When you show yourself in the world and display your talents, you naturally stir up all kinds of resentment, envy, and other manifestations of insecurity. This is to be expected. You cannot spend your life worrying about the petty feelings of others. With those above you, however, you must take a different approach: When it comes to power, outshining the master is perhaps the worst mistake of all.

Almost everyone, including you, wants to seem more brilliant than we rightly deserve. And we don’t like people to remind us of our fallibility.

Those who attain high standing in life are like kings and queens: They want to feel secure in their positions, and superior to those around them in intelligence, wit, and charm. It is a deadly but common misperception to believe that by displaying and vaunting your gifts and talents, you are winning the master’s affection. He may feign appreciation, but at his first opportunity he will replace you with someone less intelligent, less attractive, less threatening ...

There are two important points to consider.

1. You can outshine the master without trying;
2. Just because you’re loved, doesn’t mean you can do what you want.

Let’s explore these quickly, shall we?

Even if you are not trying, you can outshine the master just by being you. This happens easily. If your boss is particularly insecure, natural wit and charm will be enough to draw unwanted attention. If they are incompetent than obvious competence will do the trick. Either find a way to mute the side of you most likely to draw ire, or avoid people where being you is likely to naturally outshine them.

Second, never imagine that being valued or loved affords you the freedom to do what you want. Your status is only secure to the point your master is secure that they are better than you. Always leave them with this feeling. No matter what.

41. Five Rules to help you Learn to Love Volatility

Nassim Taleb's book Antifragile: Things That Gain from Disorder is having a profound impact on how I see the world.

In this adapted piece from Antifragile, which appeared in the Wall Street Journal, Taleb offers five policy rules that can help us establish antifragility as a principle of our socioeconomic life.

Rule 1: Think of the economy as being more like a cat than a washing machine.

We are victims of the post-Enlightenment view that the world functions like a sophisticated machine, to be understood like a textbook engineering problem and run by wonks. In other words, like a home appliance, not like the human body. If this were so, our institutions would have no self-healing properties and would need someone to run and micromanage them, to protect their safety, because they cannot survive on their own.

By contrast, natural or organic systems are antifragile: They need some dose of disorder in order to develop. Deprive your bones of stress and they become brittle. This denial of the antifragility of living or complex systems is the costliest mistake that we have made in modern times. Stifling natural fluctuations masks real problems, causing the explosions to be both delayed and more intense when they do take place. As with the flammable material accumulating on the forest floor in the absence of forest fires, problems hide in the absence of stressors, and the resulting cumulative harm can take on tragic proportions.

And yet our economic policy makers have often aimed for maximum stability, even for eradicating the business cycle. "No more boom and bust," as voiced by the U.K. Labor leader Gordon Brown, was the policy pursued by Alan Greenspan in order to "smooth" things out, thus micromanaging us into the current chaos. Mr. Greenspan kept trying to iron out economic fluctuations by injecting cheap money into the system, which eventually led to monstrous hidden leverage and real-estate bubbles. On this front there is now at least a glimmer of hope, in the U.K. rather than the U.S., alas: Mervyn King, governor of the Bank of England, has advocated the idea that central banks should intervene only when an economy is truly sick and should otherwise defer action.

Promoting antifragility doesn't mean that government institutions should avoid intervention altogether. In fact, a key problem with overzealous intervention is that, by depleting resources, it often results in a failure to intervene in more urgent situations, like natural disasters. So in complex systems, we should limit government (and other) interventions to important matters: The state should be there for emergency-room surgery, not nanny-style maintenance and overmedication of the patient—and it should get better at the former.

In social policy, when we provide a safety net, it should be designed to help people take more entrepreneurial risks, not to turn them into dependents. This doesn't mean that we should be callous to the underprivileged. In the long run, bailing out people is less harmful to the system than bailing out firms; we should have policies now that minimize the possibility of being forced to bail out firms in the future, with the moral hazard this entails.

Rule 2: Favor businesses that benefit from their own mistakes, not those whose mistakes percolate into the system.

Some businesses and political systems respond to stress better than others. The airline industry is set up in such a way as to make travel safer after every plane crash. A tragedy leads to the thorough examination and elimination of the cause of the problem. The same thing happens in the restaurant industry, where the quality of your next meal depends on the failure rate in the business—what kills some makes others stronger. Without the high failure rate in the restaurant business, you would be eating Soviet-style cafeteria food for your next meal out.

These industries are antifragile: The collective enterprise benefits from the fragility of the individual components, so nothing fails in vain. These businesses have properties similar

to evolution in the natural world, with a well-functioning mechanism to benefit from evolutionary pressures, one error at a time.

By contrast, every bank failure weakens the financial system, which in its current form is irremediably fragile: Errors end up becoming large and threatening. A reformed financial system would eliminate this domino effect, allowing no systemic risk from individual failures. A good starting point would be reducing the amount of debt and leverage in the economy and turning to equity financing. A firm with highly leveraged debt has no room for error; it has to be extremely good at predicting future revenues (and black swans). And when one leveraged firm fails to meet its obligations, other borrowers who need to renew their loans suffer as the chastened lenders lose their appetite to extend credit. So debt tends to make failures spread through the system.

A firm with equity financing can survive drops in income, however. Consider the abrupt deflation of the technology bubble during 2000. Because technology firms were relying on equity rather than debt, their failures didn't ripple out into the wider economy. Indeed, their failures helped to strengthen the technology sector.

Rule 3: Small is beautiful, but it is also efficient.

Experts in business and government are always talking about economies of scale. They say that increasing the size of projects and institutions brings costs savings. But the "efficient," when too large, isn't so efficient. Size produces visible benefits but also hidden risks; it increases exposure to the probability of large losses. Projects of \$100 million seem rational, but they tend to have much higher percentage overruns than projects of, say, \$10 million. Great size in itself, when it exceeds a certain threshold, produces fragility and can eradicate all the gains from economies of scale. To see how large things can be fragile, consider the difference between an elephant and a mouse: The former breaks a leg at the slightest fall, while the latter is unharmed by a drop several multiples of its height. This explains why we have so many more mice than elephants.

So we need to distribute decisions and projects across as many units as possible, which reinforces the system by spreading errors across a wider range of sources. In fact, I have argued that government decentralization would help to lower public deficits. A large part of these deficits comes from underestimating the costs of projects, and such underestimates are more severe in large, top-down governments. Compare the success of the bottom-up mechanism of canton-based decision making in Switzerland to the failures of authoritarian regimes in Soviet Russia and Baathist Iraq and Syria.

Rule 4: Trial and error beats academic knowledge.

Things that are antifragile love randomness and uncertainty, which also means—crucially—that they can learn from errors. Tinkering by trial and error has traditionally played a larger role than directed science in Western invention and innovation. Indeed, advances in theoretical science have most often emerged from technological development, which is closely tied to entrepreneurship. Just think of the number of famous college dropouts in the computer industry.

But I don't mean just any version of trial and error. There is a crucial requirement to achieve antifragility: The potential cost of errors needs to remain small; the potential gain should be large. It is the asymmetry between upside and downside that allows antifragile tinkering to benefit from disorder and uncertainty.

Perhaps because of the success of the Manhattan Project and the space program, we greatly overestimate the influence and importance of researchers and academics in technological advancement. These people write books and papers; tinkerers and engineers don't, and are thus less visible. Consider Britain, whose historic rise during the Industrial Revolution came from tinkerers who gave us innovations like iron making, the steam engine and textile manufacturing. The great names of the golden years of English science were hobbyists, not academics: Charles Darwin, Henry Cavendish, William

Parsons, the Rev. Thomas Bayes. Britain saw its decline when it switched to the model of bureaucracy-driven science.

America has emulated this earlier model, in the invention of everything from cybernetics to the pricing formulas for derivatives. They were developed by practitioners in trial-and-error mode, drawing continuous feedback from reality. To promote antifragility, we must recognize that there is an inverse relationship between the amount of formal education that a culture supports and its volume of trial-and-error by tinkering. Innovation doesn't require theoretical instruction, what I like to compare to "lecturing birds on how to fly."

Rule 5: Decision makers must have skin in the game.

At no time in the history of humankind have more positions of power been assigned to people who don't take personal risks. But the idea of incentive in capitalism demands some comparable form of disincentive. In the business world, the solution is simple: Bonuses that go to managers whose firms subsequently fail should be clawed back, and there should be additional financial penalties for those who hide risks under the rug. This has an excellent precedent in the practices of the ancients. The Romans forced engineers to sleep under a bridge once it was completed.

Because our current system is so complex, it lacks elementary clarity: No regulator will know more about the hidden risks of an enterprise than the engineer who can hide exposures to rare events and be unharmed by their consequences. This rule would have saved us from the banking crisis, when bankers who loaded their balance sheets with exposures to small probability events collected bonuses during the quiet years and then transferred the harm to the taxpayer, keeping their own compensation.

In these five rules, I have sketched out only a few of the more obvious policy conclusions that we might draw from a proper appreciation of antifragility. But the significance of antifragility runs deeper. It is not just a useful heuristic for socioeconomic matters but a crucial property of life in general. Things that are antifragile only grow and improve under adversity. This dynamic can be seen not just in economic life but in the evolution of all things, from cuisine, urbanization and legal systems to our own existence as a species on this planet.

We all know that the stressors of exercise are necessary for good health, but people don't translate this insight into other domains of physical and mental well-being. We also benefit, it turns out, from occasional and intermittent hunger, short-term protein deprivation, physical discomfort and exposure to extreme cold or heat. Newspapers discuss post-traumatic stress disorder, but nobody seems to account for post-traumatic growth. Walking on smooth surfaces with "comfortable" shoes injures our feet and back musculature: We need variations in terrain.

Modernity has been obsessed with comfort and cosmetic stability, but by making ourselves too comfortable and eliminating all volatility from our lives, we do to our bodies and souls what Mr. Greenspan did to the U.S. economy: We make them fragile. We must instead learn to gain from disorder.

42. “Everyone has filters to select information that receives attention.”

These excerpts were taken from Roger Fisher’s excellent book Getting It Done: How to Lead When You’re Not in Charge.

Everyone has filters to select information that receives attention. If we don’t consciously choose them we fall back on unconscious ones. Typically these default rules for selecting data limit the useful information we receive. Like a magician’s sleight of hand, they direct attention away from true action.

Do you think that what you know is more important than what you don’t?

We often equate the information we have with the information that should guide a decision. This creates two difficulties. First, we assume that what we don’t already know isn’t worth knowing. We stop looking for information when there may still be important things to learn. Secondly, we think that because we have a certain piece of information, it should figure into the decision: “If it is true, it is relevant.” Years are spent fighting over what happened yesterday for every day that is spent figuring out what out to be done tomorrow.

Are you biased toward vivid data?

We all pay undue attention to a good story. Information that has an emotional impact gobbles up attention. Dry information is ignored. As you try to accomplish something you may find that the bankruptcy of one competitor holds your attention more than an improved product being marketed by another. At work no one has packaged important information to make it easy to take in.

Are you trapped in your own point of view?

Russians have a saying that “everyone looks at the world from the bell tower of his own village.” We all know that we tend to judge ourselves more charitably than we judge others. You notice your own contributions to a success more than those of others. You tend to minimize, even to yourself, the role you played in a failure. Because we focus on data that favor us or cast others in a bad light, we neglect large amounts of relevant information.

43. The Half-life of Facts

Facts change all the time. Smoking has gone from doctor recommended to deadly. We used to think the Earth was the center of the universe and that Pluto was a planet. For decades we were convinced that the brontosaurus was a real dinosaur.

Knowledge, like milk, has an expiry date. That's the key message behind Samuel Arbesman's excellent new book The Half-life of Facts: Why Everything We Know Has an Expiration Date.

We're bombarded with studies that seemingly prove this or that. Caffeine is good for you one day and bad for you the next. What we think we know and understand about the world is constantly changing. Nothing is immune. While big ideas are overturned infrequently, little ideas churn regularly.

As scientific knowledge grows, we end up rethinking old knowledge. Abresman calls this "a churning of knowledge." But understanding that facts change (and how they change) helps us cope in a world of constant uncertainty. We can never be too sure of what we know. In introducing this idea, Abresam writes:

Knowledge is like radioactivity. If you look at a single atom of uranium, whether it's going to decay — breaking down and unleashing its energy — is highly unpredictable. It might decay in the next second, or you might have to sit and stare at it for thousands, or perhaps even millions, of years before it breaks apart.

But when you take a chunk of uranium, itself made up of trillions upon trillions of atoms, suddenly the unpredictable becomes predictable. We know how uranium atoms work in the aggregate. As a group of atoms, uranium is highly regular. When we combine particles together, a rule of probability known as the law of large numbers takes over, and even the behavior of a tiny piece of uranium becomes understandable. If we are patient enough, half of a chunk of uranium will break down in 704 million years, like clock-work. This number — 704 million years — is a measurable amount of time, and it is known as the half-life of uranium.

It turns out that facts, when viewed as a large body of knowledge, are just as predictable. Facts, in the aggregate, have half-lives: We can measure the amount of time for half of a subject's knowledge to be overturned. There is science that explores the rates at which new facts are created, new technologies developed, and even how facts spread. How knowledge changes can be understood scientifically.

This is a powerful idea. We don't have to be at sea in a world of changing knowledge. Instead, we can understand how facts grow and change in the aggregate, just like radioactive materials. This book is a guide to the startling notion that our knowledge — even what each of us has in our head — changes in understandable and systematic ways. Why does this happen? Why does knowledge churn? In Zen and the Art of Motorcycle Maintenance, Robert Pirsig writes:

If all hypotheses cannot be tested, then the result of any experiment are inconclusive and the entire scientific method falls short of its goal of establishing proven knowledge.

About this Einstein had said, "Evolution has shown that at any given moment out of all conceivable constructions a single one has always proved itself absolutely superior to the rest," and let it go at that.

... But there it was, the whole history of science, a clear story of continuously new and changing explanations of old facts. The time spans of permanence seemed completely random, he could see no order in them. Some scientific truths seemed to last for centuries, others for less than a year. Scientific truth was not dogma, good for eternity, but a temporal quantitative entity that could be studied like anything else.

A few pages later, Pirsig continues:

The purpose of scientific method is to select a single truth from among many hypothetical truths. That, more than anything else, is what science is all about. But historically science has done exactly the opposite. Through multiplication upon multiplication of facts,

information, theories and hypotheses, it is science itself that is leading mankind from single absolute truths to multiple, indeterminate, relative ones.

With that, let's dig into how this looks. Arbesman offers an example:

A few years ago a team of scientists at a hospital in Paris decided to actually measure this (churning of knowledge). They decided to look at fields that they specialized in: cirrhosis and hepatitis, two areas that focus on liver diseases. They took nearly five hundred articles in these fields from more than fifty years and gave them to a battery of experts to examine. Each expert was charged with saying whether the paper was factual, out-of-date, or disproven, according to more recent findings. Through doing this they were able to create a simple chart (see below) that showed the amount of factual content that had persisted over the previous decades. They found something striking: a clear decay in the number of papers that were still valid.

Furthermore, they got a clear measurement of the half-life of facts in these fields by looking at where the curve crosses 50 percent on this chart: 45 years. Essentially, information is like radioactive material: Medical knowledge about cirrhosis or hepatitis takes about forty-five years for half of it to be disproven or become out-of-date.

Old knowledge, however, isn't a waste. It's not like we have to start from scratch. "Rather," writes Arbesman, "the accumulation of knowledge can then lead us to a fuller and more accurate picture of the world around us."

Isaac Asimov, in a wonderful [essay](#), uses the Earth's curvature to help explain this:

When people thought the earth was flat, they were wrong. When people thought the earth was spherical, they were wrong. But if you think that that thinking the earth is spherical is just as wrong as thinking the earth is flat, then your view is wronger than both of them put together.

When our knowledge in a field is immature, discoveries come easily and often explain the main ideas. “But there are uncountably more discoveries, although far rarer, in the tail of this distribution of discovery. As we delve deeper, whether it’s into discovering the diversity of life in the oceans or the shape of the earth, we begin to truly understand the world around us.”

So what we’re really dealing with the long tail of discovery. Our search for what’s way out at the end of that tail, while it might not be as important or as Earth-shattering as the blockbuster discoveries, can be just as exciting and surprising. Each new little piece can teach us something about what we thought was possible in the world and help us to asymptotically approach a more complete understanding of our surroundings.

In an interview with the Economist, Arbesman was asked which scientific fields decay the slowest-and fastest-and what causes that difference.

Well it depends, because these rates tend to change over time. For example, when medicine transitioned from an art to a science, its half-life was much more rapid than it is now. That said, medicine still has a very short half-life; in fact it is one of the areas where knowledge changes the fastest. One of the slowest is mathematics, because when you prove something in mathematics it is pretty much a settled matter unless someone finds an error in one of your proofs.

One thing we have seen is that the social sciences have a much faster rate of decay than the physical sciences, because in the social sciences there is a lot more “noise” at the experimental level. For instance, in physics, if you want to understand the arc of a parabola, you shoot a cannon 100 times and see where the cannonballs land. And when you do that, you are likely to find a really nice cluster around a single location. But if you are making measurements that have to do with people, things are a lot messier, because people respond to a lot of different things, and that means the effect sizes are going to be smaller.

Arbesman concludes his economist interview:

I want to show people how knowledge changes. But at the same time I want to say, now that you know how knowledge changes, you have to be on guard, so you are not shocked when your children (are) coming home to tell you that dinosaurs have feathers. You have to look things up more often and recognise that most of the stuff you learned when you were younger is not at the cutting edge. We are coming a lot closer to a true understanding of the world; we know a lot more about the universe than we did even just a few decades ago. It is not the case that just because knowledge is constantly being overturned we do not know anything. But too often, we fail to acknowledge change. Some fields are starting to recognise this. Medicine, for example, has got really good at encouraging its practitioners to stay current. A lot of medical students are taught that everything they learn is going to be obsolete soon after they graduate. There is even a website called “up to date” that constantly updates medical textbooks. In that sense we could all stand to learn from medicine; we constantly have to make an effort to explore the world anew—even if that means just looking at Wikipedia more often. And I am not just talking about dinosaurs and outer space. You see this same phenomenon with knowledge about nutrition or childcare—the stuff that has to do with how we live our lives.

Even when we find new information that contradicts what we thought we knew, we’re likely to be slow to change our minds. “A prevailing theory or paradigm is not overthrown by the accumulation of contrary evidence,” writes Richard Zeckhauser, “but rather by a new paradigm that, for whatever reasons, begins to be accepted by scientists.”

In this view, scientific scholars are subject to status quo persistence. Far from being objective decoders of the empirical evidence, scientists have decided preferences about the scientific beliefs they hold. From a psychological perspective, this preference for beliefs can be seen as a reaction to the tensions caused by cognitive dissonance.

A lot of scientific advancement happens only when the old guard dies off. Many years ago Max Planck offered this insight: “A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it.”

While we have the best intentions and our minds change slowly, a lot of what we think we know is actually just a temporary knowledge to be updated in the future by more complete knowledge. I think this is why Nassim Taleb argues that we should read Seneca and not worry about someone like Jonah Lehrer bringing us sexy narratives of the latest discoveries. It turns out most of these discoveries are based on very little data and, while they may add to our cumulative knowledge, they are not likely to be around in 10 years. The Half-life of Facts is a good read that help puts what we think we understand about the world into perspective.

Follow your curiosity and read my interview with the author. Knowing that knowledge has a half-life isn't enough, we can use this to help us determine what to read.

44. Can History Tell the Truth?

"I know it is the fashion to say," George Orwell once wrote, "that most of recorded history is lies anyway. I am willing to believe that history is for the most part inaccurate and biased, but what is peculiar to our own age is the abandonment of the idea that history could be truthfully written."

Charles Frankel in The Case For the Modern Man

An exciting Japanese movie of a few years ago, Rashomon, offers a peculiarly apt illustration of (Karl) Mannheim's central thesis (that all social thinking is inevitably determined by unconscious assumptions and unacknowledged commitments – that is, everyone views events through a limited point of view.) The movie is in the form of a story told by a woodsman, who is in despair at what he has seen and heard, and has lost all of his faith in man. He reports that a Japanese lady and her husband have been set upon in the woods by a highwayman. The lady has been raped, the husband killed. And then he repeats in turn the accounts he has overheard at the police station, where the highway man, the lady, and the dead husband, speaking through a medium, have had to tell the events that transpired. Each participant tells a different story, each subtly arranges the events in a pattern that will put his own position in the best light. As each of these stories is re-enacted before our eyes, our tension mounts. We are not sure whether what really happened was murder and rape, whether the lady was treacherous or loyal, the husband cowardly or heroic, the highwayman an aggressor or a victim. Each time we move to the next story we hope to get closer to the truth, and each time we are put off. But suddenly we seem to see an opening. For it turns out that the woodsman, who has claimed to be merely repeating the stories he overheard at the police station, has been an eyewitness to the actual scene in the forest. So the woodsman tells his story. But, once more, we hear a story which has something subtly off-center about it. A dagger is unaccounted for. And then it turns out that the woodsman has stolen it. He has not been a neutral bystander; he too is a participant.

This notation that we are all participants in what happens in human history, and that there can therefore be no such thing as objectivity about history, is the central theme, and the central problem, in Mannheim's philosophy of history. We never see what "really" happens, and in fact it makes no sense even to ask. The affairs of men take place in a hall of mirrors, each with its own angle of distortion; and all we can report is what we see in the mirrors, for there is nothing else to see. All social thinking is inevitably the thinking of men who have a role in events, feelings about them, and a limited perspective upon them. Every belief comes labeled with the date, place, and social pedigree of the man who holds it. And the idea that there is an objective truth about human affairs, independently of who asserts it, is only one element in the special perspective of liberalism.

Frankel continues

There can be no disengaged intelligence seeking a universal truth. Intelligence is inevitably earth-bound, practical and biased. The questions men ask about social affairs are always selected questions that are suggested by some particular point of view and serve some special interest. The answers men accept as satisfactory are always partial answers with an inescapable element of arbitrariness in them. And even the standards of truth that men employ are limited by the social perspectives in which they are framed. Mannheim's argument that we cannot objectively observe social affairs is based on two main lines of argument. "The first of these rests on a sharp distinction between the study of nature and the study of human affairs. The second rests on an assumption about the meaning of terms like "partiality" and "bias." Frankel goes on to look at each of those.

...

We are putting the cart before the horse when we think that a science of politics must be different from other sciences because political behavior is random and haphazard. It is not because political behavior is random and haphazard that we do not have much objective

knowledge about it. It is because we do not have much objective knowledge about it that it is random and haphazard.

Ultimately Frankel comes to doubt Mannheim.

There are obvious differences between the behavior of human beings and the behavior of physical things; but they do not justify setting these two in separate worlds, or suggesting that the ideals of truth and reason we apply to the physical sciences do not apply to the study of human history. The natural sciences after all, have also had social origins and social consequences.

45. Why Privacy Matters Even if You Have ‘Nothing to Hide’

Daniel Solove, author of Nothing to Hide: The False Tradeoff between Privacy and Security, argues that privacy matters even if you have nothing to hide.

The nothing-to-hide argument pervades discussions about privacy. The data-security expert Bruce Schneier calls it the “most common retort against privacy advocates.” The legal scholar Geoffrey Stone refers to it as an “all-too-common refrain.” In its most compelling form, it is an argument that the privacy interest is generally minimal, thus making the contest with security concerns a foreordained victory for security.

“If you’ve got nothing to hide, you’ve got nothing to fear.” While flawed, that argument is not new. It appears in Henry James’s 1888 novel, The Reverberator:

If these people had done bad things they ought to be ashamed of themselves and he couldn’t pity them, and if they hadn’t done them there was no need of making such a rumpus about other people knowing.

In the end, the nothing-to-hide argument has nothing to say.

When the nothing-to-hide argument is unpacked, and its underlying assumptions examined and challenged, we can see how it shifts the debate to its terms, then draws power from its unfair advantage. The nothing-to-hide argument speaks to some problems but not to others. It represents a singular and narrow way of conceiving of privacy, and it wins by excluding consideration of the other problems often raised with government security measures. When engaged directly, the nothing-to-hide argument can ensnare, for it forces the debate to focus on its narrow understanding of privacy. But when confronted with the plurality of privacy problems implicated by government data collection and use beyond surveillance and disclosure, the nothing-to-hide argument, in the end, has nothing to say.

46. Oliver Burkeman: The Power of Negative Thinking

“Think Positive.”

That’s what magazines and friends advise us to do in order to cope with the stress of the holiday season.

That’s the same advice that Norman Vincent Peale, author of The Power of Positive Thinking, was dispensing six decades ago. It turns out that thinking positive might not be the best way to cope with our stress.

In The Antidote: Happiness for People Who Can’t Stand Positive Thinking, Oliver Burkeman argues that we should explore an alternative to the “think positive” mantra: a counterintuitive approach that might be termed “the negative path to happiness.” The heart of this approach is to embrace uncertainty.

Burkeman writes in the WSJ:

This approach helps to explain some puzzles, such as the fact that citizens of more economically insecure countries often report greater happiness than citizens of wealthier ones. Or that many successful businesspeople reject the idea of setting firm goals.

Albert Ellis, who died in 2007, rediscovered a key insight of the Stoic philosophers: sometimes the best way to address the future is to focus on the worst-case scenario, not on the best.

Seneca the Stoic was a radical on this matter. If you feared losing your wealth, he once advised, “set aside a certain number of days, during which you shall be content with the scantiest and cheapest fare, with coarse and rough dress, saying to yourself the while: ‘Is this the condition that I feared?’”

To overcome a fear of embarrassment, Ellis told me, he advised his clients to travel on the New York subway, speaking the names of stations out loud as they passed. I’m an easily embarrassed person, so in the interest of journalistic research, I took his advice, on the Central Line of the London Underground. It was agonizing. But my overblown fears were cut down to size: I wasn’t verbally harangued or physically attacked. A few people looked at me strangely.

Just thinking in sober detail about worst-case scenarios—a technique the Stoics called “the premeditation of evils”—can help to sap the future of its anxiety-producing power. The psychologist Julie Norem estimates that about one-third of Americans instinctively use this strategy, which she terms “defensive pessimism.” Positive thinking, by contrast, is the effort to convince yourself that things will turn out fine, which can reinforce the belief that it would be absolutely terrible if they didn’t.

The Antidote is a series of journeys among people who share a single, surprising way of thinking about life. What they have in common is a hunch about human psychology: that it’s our constant effort to eliminate the negative that causes us to feel so anxious, insecure, and unhappy.

47. “We get to think the world is progressing when it is only repeating itself.”

If we pay no attention to words whatever, we may become like the isolated gentleman who invents a new perpetual-motion machine on old lines in ignorance of all previous plans, and then is surprised that it doesn't work. If we confine our attention entirely to the slang of the day, that is to say, if we devote ourselves exclusively to modern literature, we get to think the world is progressing when it is only repeating itself. In both cases we are likely to be deceived, and what is more important, to deceive others. Therefore, it is advisable for us in our own interests, quite apart from considerations of personal amusement, to concern ourselves occasionally with a certain amount of our national literature drawn from all ages. I say from all ages, because it is only when one reads what men wrote long ago that one realises how absolutely modern the best of the old things are.

48. How feeling powerless directs the narratives of our mind

In his new book Mastery, Robert Greene writes discusses how feeling powerless directs the narratives of our mind.

We live in a world that seems increasingly beyond our control. Our livelihoods are at the whim of globalized forces. The problems that we face—economic, environmental, and so on—cannot be solved by our individual actions. Our politicians are distant and unresponsive to our desires. A natural response when people feel overwhelmed is to retreat into various forms of passivity. If we don't try too much in life, if we limit our circle of action, we can give ourselves the illusion of control. The less we attempt, the less chances of failure. If we can make it look like we are not really responsible for our fate, for what happens to us in life, then our apparent powerlessness is more palatable. For this reason we become attracted to certain narratives: it is genetics that determines much of what we do; we are just products of our times; the individual is just a myth; human behavior can be reduced to statistical trends.

Many take this change in value a step further, giving their passivity a positive veneer. They romanticize the self-destructive artist who loses control of him- or herself. Anything that smacks of discipline or effort seems fussy and passé: what matters is the feeling behind the artwork, and any hint of craftsmanship or work violates this principle. They come to accept things that are made cheaply and quickly. The idea that they might have to expend much effort to get what they want has been eroded by the proliferation of devices that do so much of the work for them, fostering the idea that they deserve all of this—that it is their inherent right to have and to consume what they want. “Why bother working for years to attain mastery when we can have so much power with very little effort? Technology will solve everything.” This passivity has even assumed a moral stance: “mastery and power are evil; they are the domain of patriarchal elites who oppress us; power is inherently bad; better to opt out of the system altogether,” or at least make it look that way.

49. Wittgenstein: Reality is Shaped by the Words we Use

"Philosophy is a battle against the bewitchment of our intelligence by means of our language."

— Wittgenstein

Philosopher Bertrand Russell described Ludwig Josef Johann Wittgenstein as "the most perfect example I have ever known of genius as traditionally conceived, passionate, profound, intense, and dominating."

Wittgenstein, an Austrian philosopher, worked primarily in logic, mathematics, and the philosophy of language. He published one very short book: Tractatus Logico-Philosophicus.

The book's aim was to identify the relationship between language and reality. Interestingly, he spent the last twenty-two years of his life disputing the conclusions he wrote in *Tractatus*. "I have been forced," he wrote, "to recognize the grave mistakes in what I wrote in that first book." He started over but his life was cut short before he could publish his new conclusions.

After his death these works were assembled in a book titled Philosophical Investigations, which many people consider one of the most important books of the twentieth century.

"Wittgenstein came to believe," writes Robert Hagstrom in The Last Liberal Art, "that the meaning of words is constituted by the very function they perform within any language-game. Instead of believing there was some kind of omnipotent and separate logic to the world independent of what we observe, Wittgenstein took a step back and argued instead that the world we see is defined and given meaning by the words we choose. In short, the world is what we make of it."

To help us understand, Wittgenstein drew a very simple three-sided figure.

Wittgenstein then writes:

Take as an example the aspects of a triangle. This triangle can be seen as a triangular hole, as a solid, as a geometrical drawing, as standing on its base, as hanging from its apex; as a mountain, as a wedge, as an arrow or pointer, as an overturned object, which is meant to stand on the shorter side of the right angle, as a half parallelogram, and as various other things ... You can think now of this now of this as you look at it, can regard it now as this now as this, and then you will see it now this way, now this.

In essence, reality is shaped by the words we use.

"The words we choose," Hagstrom continues, "give meaning (description) to what we observe."

In order to further explain and/or defend our description, we in turn develop a story about what we believe is true. There is nothing wrong with storytelling. In fact, it is a very effective way of transferring ideas. If you stop and think, the way we communicate with each other is basically through a series of stories. Stories are open-ended and metaphorical rather than determinate.

We all use narratives but we must be careful doing so because they shape the way we see a problem.

50. Worldly-Wisdom from Charlie Munger

I'm a huge fan of Charlie Munger — Warren Buffett's right-hand man at Berkshire Hathaway.

For those of you unfamiliar with him, listening to his famous talk, The Psychology of Human Misjudgment will have you instantly hooked.

If that doesn't get you going, check out his two-step process for making effective decisions.

Recently Munger took to the stage at the shareholder meeting for the Daily Journal Corporation — a small company based in California that few people have heard of — where he is Chairman.

While generally, managers at shareholder meetings offer very little wisdom, Munger and Buffett are exceptions.

Here's a lengthy sampling of his comments.

Incentives of managers in tough businesses

I should tell you people a story, because you are groupies for stories. I talked recently to a man who shall go nameless. But his company was one of the great growth stocks of America.

And they had armies of PhD's in there who had mastered very difficult disciplines. And they had patents, and technology, and know how, what have you and hard to replace plants. What they make is difficult to make in a lot of different categories.

And the profits in the business are very mediocre, to put it mildly. And it isn't that it has been that badly run. It's just that everybody's learned how to make these difficult things, and there are too many of them trying to make them. It just gets terrible. And what happens then is, you're now the CEO of the place and you see it's getting tough. You view yourself as a guy that knows how to fix things. You never have a category in your mind of, "It's too tough to fix," which is a really stupid idea. You can recognize all kinds of things that are too tough to fix.

But if you don't, then you are a sucker for some narrative to say, maybe there's some company in your industry that makes something really complicated that other people can't match. And you say, "Well, I'll buy that. That solves my problem." But your friendly investment banker and your friendly management consultant want you to buy it at 30 times' earnings and 12 times' book. Of course, at that price, it won't solve your problems. And you do it anyway. After all, you've got consultants, and it gives you hope.

On thinking everyone will be successful with investments

I think the idea that everybody is going to have wonderful results from investing is inherently crazy. Nobody thinks everybody is going to have wonderful results from playing poker.

In the end, the wealth of the country is based on the productivity of the country, which only advances so fast. Of course, if you pay more and more people for not working, it's hard to see how that grows the productivity of the country.

On Making Bad Decisions

You know what Rudyard Kipling said? Treat those two imposters just the same success and failure. Of course, there's going to be some failure in making the correct decisions. Nobody bats a thousand. I think it's important to review your past stupidities so you are less likely to repeat them, but I'm not gnashing my teeth over it or suffering or enduring it. I regard it as perfectly normal to fail and make bad decisions. I think the tragedy in life is to be so timid that you don't play hard enough so you have some reverses.

The failure of General Motors

General Motors, out of the profits of their good years, they could have bought, every year, for many years, a big company. They could have bought Eli Lilly one year and Merck the next, and United Technologies. General Motors could own the world. Instead, what they declared to their shareholders was a goose egg. They took the common equity to zero.

And they would say it was all somebody else's fault. The climate was bad, the unions got powerful. Those damn Asians and Europeans were too competitive.

The truth of the matter is, their very prosperity made them weak. The dealerships got in the hands of inheritors, and the executives on the sales field go around and drink martinis with inheritors, and didn't pay enough attention to defects in their vehicles. And one thing led to another, and when they were all done the shareholders' equity went to zero.

And that was in a company that at its peak was one of the most admirable companies in the world. Take the stuff that Boss Kettering (Charles Kettering – head of research at General Motors from 1920 to 1947) had invented in the early days. Kettering was one of the most useful citizens that ever lived in America.

A self starter on a car is a wonderful thing. Under the old system, you frequently broke your arm. You would give it a crank and it would answer back by spinning backwards and breaking your arm. I would much rather push a button than have my arm broken. Nor do I have the opportunity to go and crank in the sleet and snow.

51. Competitive Strategy

An organization's core capabilities are those activities that, when performed at the highest level, enable the organization to bring its where-to-play and how-to-win choices to life. They are best understood as operating as a system of reinforcing activities— a concept first articulated by Harvard Business School's Michael Porter. Porter noted that powerful and sustainable competitive advantage is unlikely to arise from any one capability (e.g., having the best sales force in the industry or the best technology in the industry), but rather from a set of capabilities that both fit with one another (i.e., that don't conflict with one another) and actually reinforce one another (i.e., that make each other stronger than they would be alone).

For Porter, a company's "strategic position is contained in a set of tailored activities designed to deliver it." He calls the visual depiction of this set of activities an activity system. Since "competitive strategy is about being different ... [and] means deliberately choosing a different set of activities to deliver unique value," an activity system must also be distinctive from the activity systems of competitors. In his landmark 1996 article "What Is Strategy?," Porter illustrated his theory with examples from Southwest Airlines, Progressive Insurance, and The Vanguard Group, articulating the way in which each organization made distinctive choices and tailored an activity system to deliver on those choices. The activity system is a visual representation of the firm's competitive advantage, capturing on a single page the core capabilities of the firm. Articulating a firm's core capabilities is a vital step in the strategy process. Identifying the capabilities required to deliver on the where-to-play and how-to-win choices crystallizes the area of focus and investment for the company. It enables a firm to continue to invest in its current capabilities, to build up others, and to reduce the investment in capabilities that are not essential to the strategy.

53. Temperament Matters: In Life and Business

I love this excerpt from *Quiet: The Power of Introverts in a World That Can't Stop Talking* on Warren Buffett and temperament.

Buffett is known for thinking carefully when those around him are losing their heads. "Success in investing doesn't correlate with IQ," he has said. "Once you have ordinary intelligence, what you need is the temperament to control the urges that get other people into trouble in investing."

*Every summer since 1983, the boutique investment bank Allen & Co. has hosted a weeklong conference in Sun Valley, Idaho. This isn't just any conference. It's an extravaganza, with lavish parties, river-rafting trips, ice-skating, mountain biking, fly fishing, horseback riding, and a fleet of babysitters to care for guests' children. The hosts service the media industry, and past guest lists have included newspaper moguls, Hollywood celebrities, and Silicon Valley stars, with marquee names such as Tom Hanks, Candice Bergen, Barry Diller, Rupert Murdoch, Steve Jobs, Diane Sawyer, and Tom Brokaw. In July 1999, according to Alice Schroeder's excellent biography of Buffett, *The Snowball*, he was one of those guests. He had attended year after year with his entire family in tow, arriving by Gulfstream jet and staying with the other VIP attendees in a select group of condos overlooking the golf course. Buffett loved his annual vacation at Sun Valley, regarding it as a great place for his family to gather and for him to catch up with old friends.*

But this year the mood was different. It was the height of the technology boom, and there were new faces at the table—the heads of technology companies that had grown rich and powerful almost overnight, and the venture capitalists who had fed them cash. These people were riding high. When the celebrity photographer Annie Leibovitz showed up to shoot "the Media All-Star Team" for Vanity Fair, some of them lobbied to get in the photo. They were the future, they believed.

Buffett was decidedly not a part of this group. He was an old-school investor who didn't get caught up in speculative frenzy around companies with unclear earnings prospects. Some dismissed him as a relic of the past. But Buffett was still powerful enough to give the keynote address on the final day of the conference.

He thought long and hard about that speech and spent weeks preparing for it. After warming up the crowd with a charmingly self-deprecating story—Buffett used to dread public speaking until he took a Dale Carnegie course—he told the crowd, in painstaking, brilliantly analyzed detail, why the tech-fueled bull market wouldn't last. Buffett had studied the data, noted the danger signals, and then paused and reflected on what they meant. It was the first public forecast he had made in thirty years.

The audience wasn't thrilled, according to Schroeder. Buffett was raining on their parade. They gave him a standing ovation, but in private, many dismissed his ideas. "Good old Warren," they said. "Smart man, but this time he missed the boat."

Later that evening, the conference wrapped up with a glorious display of fireworks. As always, it had been a blazing success. But the most important aspect of the gathering—Warren Buffett alerting the crowd to the market's warning signs—wouldn't be revealed until the following year, when the dot-com bubble burst, just as he said it would.

Buffett takes pride not only in his track record, but also in following his own "inner scorecard." He divides the world into people who focus on their own instincts and those who follow the herd. "I feel like I'm on my back," says Buffett about his life as an investor, "and there's the Sistine Chapel, and I'm painting away. I like it when people say, 'Gee, that's a pretty good-looking painting.' But it's my painting, and when somebody says, 'Why don't you use more red instead of blue?' Good-bye. It's my painting. And I don't care what they sell it for. The painting itself will never be finished. That's one of the great things about it."

Temperament is what caused Buffett to go into insurance. In *The Snowball*, Schroeder writes:

He loved the handicapping aspect, the tough negotiating in which temperament mattered and huge sums of money were won or lost based on pure intellect and will. This business in which psychology gave the right person an edge drew together all of Buffett's skills.

Unfinished thought

It's Buffett's comment that really sticks with me because, like a lot of his wisdom, it transcends investing and remains true in many aspects of life.

Success in investing doesn't correlate with IQ. Once you have ordinary intelligence, what you need is the temperament to control the urges that get other people into trouble in investing

Warren Buffett

Temperament matters.

You need a temperament that controls the urges that get other people into trouble. And there is a long list of things that get people into trouble ... Buffett offers a great example:

You need a temperament that neither derives great pleasure from being with the crowd or against the crowd.

You also need a temperament that allows you to take action, whereas many just sit and watch. In his 1993 shareholder letter, Buffett writes:

a director who sees something he doesn't like should attempt to persuade the other directors of his views. If he is successful, the board will have the muscle to make the appropriate change. Suppose, though, that the unhappy director can't get other directors to agree with him. He should then feel free to make his views known to the absentee owners. Directors seldom do that, of course. The temperament of many directors would in fact be incompatible with critical behavior of that sort. But I see nothing improper in such actions, assuming the issues are serious. Naturally, the complaining director can expect a vigorous rebuttal from the unpersuaded directors, a prospect that should discourage the dissenter from pursuing trivial or non-rational causes.

The temperament of many people is incompatible with critical behavior. Most people go with the path of least resistance.

Take the high road, you'll find it's less crowded.

charlie munger

Temperament affects so much, and yet we rarely give it thought.

54. Opinions and Organizational Theory

When I think about the world in which we live and the organizations in which we work, I can't help but think that few people have the intellectual honesty, time, and discipline required to hold a view. Considered opinions are a lot of work, that's why there are so few of them.

We have a bias for action and, equally important, a bias for the appearance of knowledge. Think about it. When's the last time you heard someone say *I don't know*? If my experience was any indication, it seems the higher up the corporate ladder you go, the more unlikely you are to say or hear those three words.

Too Busy to Think

No one wants to tell the boss they don't know. The boss certainly doesn't want to let on that they might know either. We have too much of our self-worth wrapped up in our profession and others opinions of us.

Because we don't know, we talk in abstractions and fog. The appearance of knowledge becomes our currency.

Who has time to do the work required to hold an opinion? There is always an email to respond to, an urgent request from your boss, paper to move from one side of your desk to the other, etc. So we don't do the work. But so few others do the work either.

Perhaps an example will help.

At 4:45 pm you receive a 4 page proposal in your inbox. The proposal is to be decided on the next day at a meeting with 12 people.

To reflect on the proposal seriously, you'd have to stay at work late. You'd need to turn off the email and all of your other tasks to read a document from start to finish. And, after-all, who has time to read four pages these days? (So we skim.)

If we really wanted to do the work necessary to hold an opinion we'd have to: read the document from start to finish; talk to anyone you can find about the proposal; listen to arguments from others for and against it; verify the facts; consider our assumptions; talk to someone who has been through something similar before; verify the framing of the problem is not too narrow or wide; make sure the solution solves the problem; etc.

So we don't do the work. Yet we need an opinion for the meeting, or, perhaps more accurately, a sound bite. So we skim the document again looking for something we can support; something that signals we've thought about it, despite the fact we haven't.

We spend the time we should be learning and understanding something running around trying to make it look like we know everything. We're doing work alright: busywork.

We turn up at the meeting the next day to discuss the proposal but our only real goal is to find a brief pause in the conversation so we can insert our pre-scripted, fact-deficient, obfuscating generality into the conversation. We do, after-all, have to maintain appearances.

The proposal ultimately reaches consensus, but this was never really in doubt. If you flip this around for a second, it must be the easiest decision in the world. Think about it, here you have a room full of smart people all in agreement on the best way to proceed. How often does that happen? A true no-brainer is hardly worth a memo or even a meeting.

It's easy to agree when no one is thinking.

And organizational incentives encourage this behavior.

If the group makes the right decision you can take take credit. And, if by chance things go wrong, you don't get the blame. Group decisions, especially ones with consensus, allow for all of the participants to have the upside and few if any to have the downside.

When groups make decisions based on consensus, no one is really accountable if things go bad. Everyone can weasel out of responsibility (diffusion of responsibility).

When you're talking to someone familiar with the situation you might say something like, 'we were all wrong' or 'we all thought the same thing.'

When you're talking to someone unfamiliar with the situation you'd offer something more clever like 'I thought that decision was wrong but no one would listen to me,' knowing full well they can't prove you wrong.

And just like that, one-by-one, everyone in attendance at the meeting is absolved.

The alternative is uncomfortable.

Say, rather than jetting off to pick up the kids at 5 you stay and do the work required to have an opinion. While you get home around 11, exhausted, you are now comfortable with a well thought out opinion on the proposal. Maybe two things happen at this point. If you've done the work and you reached the same conclusion at the proposal, you feel like you just wasted 6 hours. If, however, you do the work and you reach a different conclusion, things get more interesting.

You show up at the meeting and mention that you thought about this and reached a different conclusion — In fact, you determine this proposal doesn't solve the problem. It's nothing more than lipstick.

So you speak up. And in the process, you risk being labelled as a dissenting troublemaker. Why, because no one else has done the work.

You might even offer some logical flow for everyone to follow along with your thinking. So you say something along the lines of: "I think a little differently on this. Here is how I see the problem and here are what I think are the governing variables. And here is how I weighed them. And here is how I'd address the main arguments I see against this. ... What I'd miss?"

In short you'd expose your thinking and open yourself up. You'd be vulnerable to people who haven't really done the work.

If you expect them to say OK, that sounds good, you'd be wrong. After all, if they're so easily swayed by your rational thinking, it looks like they haven't done the work.

Instead, they need to show they've already thought about your reasoning and arguments and formed a different opinion.

Rather than stick to facts, they might respond with hard to pin down jargon or corporate speak — facts will rarely surface in a rebuttal.

You'll hear something like "that doesn't account for the synergies" or "that doesn't line up with the strategic plan (you haven't seen)." Or maybe they point the finger at their boss who is not in the room: "That's what I thought too but Doug, oh no, he wants it done this way."

If you push too far you won't be at the next meeting because everyone knows you'll do the work and that means they know that by inviting you they'll be forced to think about things a little more, to anticipate arguments, etc. In short, inviting you means more work for them. It's nothing personal.

55. Intelligent Preparation: The World Is Multidisciplinary

We live in a society that demands specialization. Being the best means being an expert in something. Letters after your name and decades in the trenches of experience are required before you can claim to know anything. In one sense there is nothing wrong with this — specialized knowledge is required to solve problems and advance our global potential. But a byproduct of this niche focus is that it narrows the ways we think we can apply our knowledge without being called a fraud.

So we think physicists can't teach us about love; mathematicians can't instruct us on how to run a business; poets don't know squat about "my life." And bloggers can't contribute to philosophy.

I don't believe this is true.

Knowledge is hard to come by.

It takes work and commitment, and I think we owe it to ourselves to take it out of the box it comes in and experiment with it. We should blow past conformity and apply all the knowledge at our disposal to the problems and challenges we face every day.

Think about it. Over time you've picked up a lot of fundamentals about how the world works. You may have read a book about the Manhattan Project and the building of the nuclear bomb that was launched at Hiroshima. This story conveys the awesome power of self-sustaining nuclear reactions. Have you ever thought about applying those ideas to your life? You should.

56. The Fragilista

They think that the reasons for something are immediately accessible to them, even if they have no clue.

No matter how complex or difficult, no problem results in an “I don’t know.”

They are the fragilista.

Frequently found wearing suits and spending a lot of time in meetings, they prefer to tinker with things they do not understand rather than doing nothing.

This isn’t my idea, it’s Nassim Taleb’s.

In *Antifragile: Things That Gain from Disorder*, he writes:

[The fragilista] defaults to thinking that what he doesn’t see is not there, or what he does not understand does not exist. At the core, he tends to mistake the unknown for the nonexistent.

Fragilistas are naive rationalists.

They think that the reasons for things are, by default, accessible to them. They know the cause and effect of everything, or at least that’s what they think.

Because they mistake what they don’t know for the non-existent, they exhibit a strong — if mistaken — regard for the powers of reason.

They lack humility and respect for the first law of ecology: we can never do merely one thing.

Any action we take, and in this case inaction is a course of action, results in some unwanted consequences.

According to Taleb, the problem with the fragilista is that they “*make you engage in policies and actions, all artificial, in which the benefits are small and visible, and the side effects (are) potentially severe and invisible.*”

Fragilistas are everywhere.

They are the doctors who intervene too much in the body’s natural ability to heal, prescribing powerful medications with small benefit and possibly severe side effects.

There is the management fragilista who: (1) introduces a bureaucratic solution to what is really a people problem; (2) manages by best-seller; (3) seeks refuge in the false security of best-practices; (4) fails to come up with reasonable benchmarks for judging performance of solutions; (5) does everything and thus does nothing; etc.

There is the policy fragilista who feels that continuous interventions into the financial market are necessary for stability.

In *Filters Against Folly*, Garrett Hardin writes:

Whatever plan of action we adopt in our attempt to remake the world, our usual first step is to pin a laudatory label on what we are doing. We may call it development, cure, correction, improvement, help, or progress. We load untested conclusions onto ill-stated premises. But every intervention in an existing system is, for certain, only an intervention. We will make progress faster if we honestly call the changes “interventions” only, until an audit shows what we have actually done. Needless to say, such honesty will be resisted by most promoters of change.

The point isn’t to avoid risk or even intervention but rather to be humble about our knowledge, or lack of it.

To know when we should avoid small, immediate, and visible benefits that introduce the possibility for large (and possibly invisible) side effects. Less is more.

This isn’t foolproof but one possible way to counter the fragilista is to ensure rationale is explicitly (and publicly) stated up front.

When we mess with an existing (complex) system we’re intervening; we can never do merely one thing.

57. Naive Realism — I’m Right; You’re Biased

We're good at spotting others' faults while ignoring our own.

If someone informed you of your biases do you think you'd change your response?

Not likely. Even when we know about our biases and we're asked 'do you want to change what you just said' the results are the same.

We're happy to learn about biases, we even apply this knowledge to better predict the behavior of others. However, when it comes to ourselves, we're unmoved.

You probably think you're an above average driver.

Now I can shake you and tell you that most people have an inflated view of themselves. I can tell you that you're biased. I can tell you to be realistic.

And you're still going to look at me and say "*Other people* may be biased but I *really am* an above average driver."

Why is this? Emily Pronin at Princeton and Lee Ross at Stanford trace our resistance to self-awareness to a phenomenon they call naive realism.

From The Happiness Hypothesis:

Each of us thinks we see the world directly, as it really is.

We further believe that the facts as we see them are there for all to see, therefore others should agree with us.

If they don't agree, it follows either that they have not yet been exposed to the relevant facts or else that they are blinded by their interests and ideologies.

People acknowledge that their own backgrounds have shaped their views, but such experiences are invariably seen as deepening one's insights; for example, being a doctor gives a person special insight into the problems of the health-care industry. But the background of other people is used to explain their biases and covert motivations; for example, doctors think that lawyers disagree with them about tort reform not because they work with the victims of malpractice (and therefore have their own special insights) but because their self-interest biases their thinking.

It just seems plain as day, to the naive realist, that everyone is influenced by ideology and self-interest. Except for me. I see things as they are.

It's so easy for this to move from the individual to the group level. My group is right because we see things as they are and your group is wrong because you are biased by your ideology, religion, or self-interest.

58. Atul Gawande: Why We Fail

“Failures of ignorance we can forgive. If the knowledge of the best thing to do in a given situation does not exist, we are happy to have people simply make their best effort. But if the knowledge exists and is not applied correctly, it is difficult not to be infuriated.”

— Atul Gawande

We fail for two reasons. The first is ignorance, and the second is ineptitude. In The Checklist Manifesto: How to Get Things Right, Atul Gawande explains:

In the 1970s, the philosophers Samuel Gorovitz and Alasdair MacIntyre published a short essay on the nature of human fallibility that I read during my surgical training and haven't stopped pondering since. The question they sought to answer was why we fail at what we set out to do in the world. One reason, they observed, is “necessary fallibility” — some things we want to do are simply beyond our capacity. We are not omniscient or all-powerful. Even enhanced by technology, our physical and mental powers are limited. Much of the world and universe is—and will remain—outside our understanding and control.

There are substantial realms, however, in which control is within our reach. We can build skyscrapers, predict snowstorms, save people from heart attacks and stab wounds. In such realms, Gorovitz and MacIntyre point out, we have just two reasons that we may nonetheless fail.

The first is ignorance—we may err because science has given us only a partial understanding of the world and how it works. There are skyscrapers we do not yet know how to build, snowstorms we cannot predict, heart attacks we still haven't learned how to stop. The second type of failure the philosophers call ineptitude—because in these instances the knowledge exists, yet we fail to apply it correctly. This is the skyscraper that is built wrong and collapses, the snowstorm whose signs the meteorologist just plain missed, the stab wound from a weapon the doctors forgot to ask about.

For most of history, we've failed because of ignorance. We had only a partial understanding of how things worked.

In Taking the Medicine, Druin Burch writes:

Doctors, for most of human history, have killed their patients far more often than they have saved them. Their drugs and their advice have been poisonous. They have been sincere, well-meaning and murderous.

We used to know very little about the illnesses that befell us and even less about how to treat them. But, for the most part, that's changed. Over the last several decades, our knowledge has improved. This advance means that ineptitude plays a more central role in failure than ever before.

Heart attacks are a great example. “Even as recently as the 1950s,” Gawande writes, “we had little idea of how to prevent or treat them.” Back then, and some would argue even today, we knew very little about what caused heart attacks. Worse, even if we had been aware of the causes, we probably wouldn't have known what to do about it. Sure we'd give people morphine for pain and put people on bed rest, to the point where people couldn't even get out of bed to use the bathroom. We didn't want to stress a damaged heart. When knowledge doesn't exist, we do what we've always done. We pray and cross our fingers. Fast-forward to today and Gawande says “we have at least a dozen effective ways to reduce your likelihood of having a heart attack—for instance, controlling your blood pressure, prescribing a statin to lower cholesterol and inflammation, limiting blood sugar levels, encouraging exercise regularly, helping with smoking cessation, and, if there are early signs of heart disease, getting you to a cardiologist for still further recommendations.” *If you should have a heart attack, we have a whole panel of effective therapies that can not only save your life but also limit the damage to your heart: we have clot-busting drugs that can reopen your blocked coronary arteries; we have cardiac catheters that can*

balloon them open; we have open heart surgery techniques that let us bypass the obstructed vessels; and we've learned that in some instances all we really have to do is send you to bed with some oxygen, an aspirin, a statin, and blood pressure medications—in a couple days you'll generally be ready to go home and gradually back to your usual life. Today we know more about heart attacks but, according to Gawande, the odds a hospital deals with them correctly and in time are less than 50%. We know what we should do, and we still don't do it.

So if we know so much, why do we fail? The problem today is ineptitude. Or, maybe, simply “eptitude” — applying knowledge correctly and consistently.

The modern world has dumped a lot of complexity on us, and we're struggling to keep our heads above water. Not only is the complexity of knowledge increasing, but so is the velocity. The world is getting more complex. This challenge is not limited to medicine. It applies to nearly everything.

Know-how and sophistication have increased remarkably across almost all our realms of endeavor, and as a result so has our struggle to deliver on them. You see it in the frequent mistakes authorities make when hurricanes or tornadoes or other disasters hit. You see it in the 36 percent increase between 2004 and 2007 in lawsuits against attorneys for legal mistakes—the most common being simple administrative errors, like missed calendar dates and clerical screw ups, as well as errors in applying the law. You see it in flawed software design, in foreign intelligence failures, in our tottering banks—in fact, in almost any endeavor requiring mastery of complexity and of large amounts of knowledge.

Such failures carry an emotional valence that seems to cloud how we think about them. Failures of ignorance we can forgive. If the knowledge of the best thing to do in a given situation does not exist, we are happy to have people simply make their best effort. But if the knowledge exists and is not applied correctly, it is difficult not to be infuriated. What do you mean half of heart attack patients don't get their treatment on time? What do you mean that two-thirds of death penalty cases are overturned because of errors? It is not for nothing that the philosophers gave these failures so unmerciful a name—ineptitude. Those on the receiving end use other words, like negligence or even heartlessness.

Those of us who make mistakes where knowledge is known, feel like these judgments ignore how difficult today's jobs are. Failure wasn't intentional, and the situation is not as black and white.

Today there is more to know, more to manage, more to keep track of. More systems to learn and unlearn as new ones come online. More emails. More calls. More distractions. On top of that, there is more to get right and more to learn. And this, of course, creates more opportunities for mistakes.

Our typical response, rather than recognizing the inherent complexity of the system by which judgments are made, is to increase training and experience. Doctors, for example, go to school for many years. Engineers too. Accountants the same. And countless others. All of these professions have certifications, continuous training, some method of apprenticeship. You need to practice to achieve mastery.

In the medical field, training is longer and more intense than ever. Yet preventable failures remain.

So here we are today, the start of the twenty-first century. We have more knowledge than ever. We put that knowledge into the hands of people who are the most highly trained, hardest working, and skilled people we can find. Doing so has created impressive outcomes. As a society, we've done some amazing things.

Yet despite this, avoidable failures are common and persistent. Organizations make poor mistakes even when knowledge exists that would lead them to make different decisions. People do the same. The know-how has somehow become unmanageable. Perhaps, the

velocity and complexity of information have exceeded our individual ability to deal with it. We are becoming inept.

Gawande's solution to deal with ineptitude is a checklist. The Checklist Manifesto: How to Get Things Right is fascinating and eye-opening in its entirety.

59. Scarcity: Why Having Too Little Means So Much

“The biggest mistake we make about scarcity is we view it as a physical phenomenon. It’s not.”

We’re busier than ever. The typical inbox is perpetually swelling with messages awaiting attention. Meetings need to be rescheduled because something came up. Our relationships suffer. We don’t spend as much time as we should with those who mean something to us. We have little time for new people; potential friends eventually get the hint and stop proposing ideas for things to do together. Falling behind, turns into a vicious cycle.

Does this sound anything like your life?

You have something in common with people who fall behind on their bills, argue Harvard economist Sendhil Mullainathan and Princeton psychologist Eldar Shafir in their book Scarcity: Why Having Too Little Means So Much. The resemblance, they write, is clear.

Missed deadlines are a lot like over-due bills. Double-booked meetings (committing time you do not have) are a lot like bounced checks (spending money you do not have). The busier you are, the greater the need to say no. The more indebted you are, the greater the need to not buy. Plans to escape sound reasonable but prove hard to implement. They require constant vigilance—about what to buy or what to agree to do. When vigilance flags—the slightest temptation in time or in money—you sink deeper.

Some people end up sinking further into debt. Others with more commitments. The resemblance is striking.

We normally think of time management and money management as distinct problems. The consequences of failing are different: bad time management leads to embarrassment or poor job performance; bad money management leads to fees or eviction. The cultural contexts are different: falling behind and missing a deadline means one thing to a busy professional; falling behind and missing a debt payment means something else to an urban low-wage worker.

What’s common between these situations? Scarcity. “By scarcity,” they write, “we mean having less than you feel you need.”

And what happens when we feel a sense of scarcity? To show us Mullainathan and Shafir bring us back to the past. Near the end of World War II, the Allies realized they would need to feed a lot of Europeans on the edge of starvation. The question wasn’t where to get the food but, rather, something more technical. What is the best way to start feeding them?

Should you begin with normal meals or small quantities that gradually increase?

Researchers at the University of Minnesota undertook an experiment with healthy male volunteers in a controlled environment “where their calories were reduced until they were subsisting on just enough food so as not to permanently harm themselves.” The most surprising findings were psychological. The men became completely focused on food in unexpected ways:

Obsessions developed around cookbooks and menus from local restaurants. Some men could spend hours comparing the prices of fruits and vegetables from one newspaper to the next. Some planned now to go into agriculture. They dreamed of new careers as restaurant owners.... When they went to the movies, only the scenes with food held their interest.

“Scarcity captures the mind,” Mullainathan and Shafir write. Starving people have food on their mind to the point of irrationality. But we all act this way when we experience scarcity. “The mind,” they write, “orients automatically, powerfully, toward unfulfilled needs.”

Scarcity is like oxygen. When you don’t need it, you don’t notice it. When you do need it, however, it’s all you notice.

For the hungry, that need is food. For the busy it might be a project that needs to be finished. For the cash-strapped it might be this month’s rent payment; for the lonely, a lack

of companionship. Scarcity is more than just the displeasure of having very little. It changes how we think. It imposes itself on our minds.

And when scarcity is taking up your mental cycles and putting your attention on what you lack, you can't attend to other things. How, for instance, can you learn?

(There was) a school in New Haven that was located next to a noisy railroad line. To measure the impact of this noise on academic performance, two researchers noted that only one side of the school faced the tracks, so the students in classrooms on that side were particularly exposed to the noise but were otherwise similar to their fellow students. They found a striking difference between the two sides of the school. Sixth graders on the train side were a full year behind their counterparts on the quieter side. Further evidence came when the city, prompted by this study, installed noise pads. The researchers found this erased the difference: now students on both sides of the building performed at the same level.

Cognitive load matters. Mullainathan and Shafir believe that scarcity imposes a similar mental tax, impairing our ability to perform well, and exercise self-control.

We are all susceptible to "the planning fallacy," which means that we're too optimistic about how long it will take to complete a project. Busy people, however, are more vulnerable to this fallacy. Because they are focused on everything they must currently do, they are "more distracted and overwhelmed—a surefire way to misplan." "The underlying problem," writes Cass Sunstein in his review for the New York Review of Books, "is that when people tunnel, they focus on their immediate problem; 'knowing you will be hungry next month does not capture your attention the same way that being hungry today does.' A behavioral consequence of scarcity is "juggling," which prevents long-term planning."

When we have abundance, we don't have as much depletion. Wealthy people can weather a shock without turning their lives upside-down. The mental energy needed to prevail may be substantial, but it will not create a feeling of scarcity.

Imagine a day at work where your calendar is sprinkled with a few meetings and your to-do list is manageable. You spend the unscheduled time by lingering at lunch or at a meeting or calling a colleague to catch up. Now, imagine another day at work where your calendar is chock-full of meetings. What little free time you have must be sunk into a project that is overdue. In both cases time was physically scarce. You had the same number of hours at work and you had more than enough activities to fill them. Yet in one case you were acutely aware of scarcity, of the finiteness of time; in the other it was a distant reality, if you felt it at all. The feeling of scarcity is distinct from its physical reality.

Mullainathan and Shafir sum up their argument:

In a way, our argument in this book is quite simple. Scarcity captures our attention, and this provides a narrow benefit: we do a better job of managing pressing needs. But more broadly, it costs us: we neglect other concerns, and we become less effective in the rest of life. This argument not only helps explain how scarcity shapes our behaviors; it also produces some surprising results and sheds new light on how we might go about managing our scarcity.

In a way, this explains why diets never work.

60. The Hard Thing About Hard Things

The problem with most business books is they present a formula for problems that ultimately have no formula. You're reading something with no practical value and you're not really learning anything. There is no formula for dealing with complexity that's always changing. "There's no recipe for leading a group of people out of trouble," writes Ben Horowitz in *The Hard Thing About Hard Things*. The book is one of the best business books I've read in a long time.

The hard thing isn't setting a big, hairy, audacious goal. The hard thing is laying people off when you miss the big goal. The hard thing isn't hiring great people. The hard thing is when those "great people" develop a sense of entitlement and start demanding unreasonable things. The hard thing isn't setting up an organizational chart. The hard thing is getting people to communicate within the organization that you just designed. The hard thing isn't dreaming big. The hard thing is waking up in the middle of the night in a cold sweat when the dream turns into a nightmare.

Most management books focus on how to avoid screwing up — or at least covering your ass if you do. Ben, however, provides insight into what to do after you screw up. and you will screw up.

Just because there is no formula doesn't mean things are hopeless. Advice and experience can help guide us. But that's the difference between Ben's book and most: he shows you what it's really like to make hard decisions, without offering you a three-step formula. Horowitz walks you through his considerations, deliberations, thoughts, mistakes, regrets, difficulties. Through that journey, we learn. "Circumstances may differ, but the deeper patterns and the lessons keep resonating."

Fear can be good.

Here is an interesting point on fear that's representative and telling of the book.

... It taught me that being scared didn't mean I was gutless. What I did mattered and would determine whether I would be a hero or a coward. I have often thought back on that day, realizing that if I'd done what Roger had told me to do, I would have never met my best friend. That experience also taught me not to judge things by their surfaces. Until you make the effort to get to know someone or something, you don't know anything. There are no shortcuts to knowledge, especially knowledge gained from personal experience. Following conventional wisdom and relying on shortcuts can be worse than knowing nothing at all.

Seeing the world through different lenses.

Looking at the world through such different prisms helped me separate facts from perception. This ability would serve me incredibly well later when I became an entrepreneur and CEO. In particularly dire circumstances when the "facts" seemed to dictate a certain outcome, I learned to look for alternative narratives and explanations coming from radically different perspectives to inform my outlook. The simple existence of an alternate, plausible scenario is often all that's needed to keep hope alive among a worried workforce.

We can't do everything.

My father turned to me and said, "Son, do you know what's cheap?"

Since I had absolutely no idea what he was talking about, I replied, "No, what?"

"Flowers. Flowers are really cheap. But do you know what's expensive?" he asked.

Again, I replied, "No, what?" He said, "Divorce."

Something about that joke, which was not really a joke, made me realize that I had run out of time. Up until that point, I had not really made any serious choices. I felt like I had unlimited bandwidth and could do everything in life that I wanted to do simultaneously. But his joke made it suddenly clear that by continuing on the course I was on, I might lose my family. By doing everything, I would fail at the most important thing. It was the first time that I forced myself to look at the world through priorities that were not purely my own. I thought

that I could pursue my career, all my interests, and build my family. More important, I always thought about myself first. When you are part of a family or part of a group, that kind of thinking can get you into trouble, and I was in deep trouble. In my mind, I was confident that I was a good person and not selfish, but my actions said otherwise.

The best thing about startups.

Marc (Andreessen): *"Do you know the best thing about startups?"*

Ben: *"What?"*

Marc: *"You only ever experience two emotions: euphoria and terror. And I find that lack of sleep enhances them both."*

The type of friends you need in your life.

No matter who you are, you need two kinds of friends in your life. The first kind is one you can call when something good happens, and you need someone who will be excited for you. Not a fake excitement veiling envy, but a real excitement. You need someone who will actually be more excited for you than he would be if it had happened to him. The second kind of friend is somebody you can call when things go horribly wrong—when your life is on the line and you only have one phone call. Who is it going to be?

Doing hard things, not fun things.

Ben had a lot of mentors, Bill Campbell was one of them. Being present and letting people know where they stand is incredibly important. Four-star General Stan McChrystal couldn't have been the leader he was without being out there with the troops sleeping in the same conditions with the same risk. Here is an incredibly important lesson on leadership that most people miss.

After seven weeks, we came to an agreement with EDS. They would buy Loudcloud for \$ 63.5 million in cash and assume its associated liabilities and cash burn. We would retain the intellectual property, Opsware, and become a software company. EDS would then license our software to run both Loudcloud and the larger EDS for \$ 20 million per year. I thought it was a great deal for both EDS and us. It was certainly far better than bankruptcy. I felt 150 pounds lighter. I could take a deep breath for the first time in eighteen months. Still, it wouldn't be easy. Selling Loudcloud meant selling about 150 employees to EDS and laying off another 140.

I called Bill Campbell to tell him the good news: The deal was signed and we would be announcing it in New York on Monday. He replied, "Too bad you can't go to New York and be part of the announcement; you'll have to send Marc." I said, "What do you mean?" He said, "You need to stay home and make sure everybody knows where they stand. You can't wait a day. In fact, you can't wait a minute. They need to know whether they are working for you, EDS, or looking for a fucking job." Damn. He was right. I sent Marc to New York and prepared to let people know where they stood. That small piece of advice from Bill proved to be the foundation we needed to rebuild the company. If we hadn't treated the people who were leaving fairly, the people who stayed would never have trusted me again. Only a CEO who had been through some awful, horrible, devastating circumstances would know to give that advice at that time.

Figuring out what the customer wants is the innovator's job. And innovation requires a combination of skills.

It turns out that is exactly what product strategy is all about—figuring out the right product is the innovator's job, not the customer's job. The customer only knows what she thinks she wants based on her experience with the current product. The innovator can take into account everything that's possible, but often must go against what she knows to be true. As a result, innovation requires a combination of knowledge, skill, and courage.

I've talked about the important role that coding will play in the future. Horowitz offers a simple lesson for programmers and managers alike: "all decisions were objective until the first line of code was written. After that, all decisions were emotional."

Tell it like it is.

When you start losing the truth is the first thing to go and everyone sees it. *One of the most important management lessons for a founder/ CEO is totally unintuitive. My single biggest personal improvement as CEO occurred on the day when I stopped being too positive.*

As a young CEO, I felt the pressure—the pressure of employees depending on me, the pressure of not really knowing what I was doing, the pressure of being responsible for tens of millions of dollars of other people's money. As a consequence of this pressure, I took losses extremely hard. If we failed to win a customer or slipped a date or shipped a product that wasn't quite right, it weighed heavily on me. I thought that I would make the problem worse by transferring that burden to my employees. Instead, I thought I should project a positive, sunny demeanor and rally the unburdened troops to victory. I was completely wrong.

I realized my error during a conversation with my brother in-law, Cartheu. At the time, Cartheu worked for AT& T as a telephone lineman (he is one of those guys who climb the poles). I had just met a senior executive at AT& T, whom I'll call Fred, and I was excited to find out if Cartheu knew him. Cartheu said, "Yeah, I know Fred. He comes by about once a quarter to blow a little sunshine up my ass." At that moment, I knew that I'd been screwing up my company by being too positive.

Why should you tell it like it is?

A few reasons: it builds trust; smart people will see through the lies anyway; it fosters a positive culture and ensures everyone is working from the same page with the same information. The pressure to be positive as a leader is incredible. People are looking to you and you want to inspire them. But the best way to do that is to be real with them. For example, if you're trying to foster a culture where failure is ok, but you don't get up there and talk about one of your massive personal failures, the culture won't even have a chance to change.

The Hard Thing About Hard Things is the best business book I've read in a long time. Perhaps one of the best ever.

61. The Art of Winning An Argument

We spend a lot of our lives trying to convince or persuade others to our point of view. This is one of the reasons that Daniel Pink says that we're all in sales:

Some of you, no doubt, are selling in the literal sense—convincing existing customers and fresh prospects to buy casualty insurance or consulting services or homemade pies at a farmers' market. But all of you are likely spending more time than you realize selling in a broader sense—pitching colleagues, persuading funders, cajoling kids. Like it or not, we're all in sales now.

Persuade or Convince?

But ... how are we to change minds? What's the best way to win an argument? Should we try to convince people, or should we try to persuade them?

In the difference between persuading and convincing, Seth Godin writes:

Marketers don't convince. Engineers convince. Marketers persuade. Persuasion appeals to the emotions and to fear and to the imagination. Convincing requires a spreadsheet or some other rational device.

It's much easier to persuade someone if they're already convinced, if they already know the facts. But it's impossible to change someone's mind merely by convincing them of your point.

Sometimes people just disagree. And it's here where we things start to get interesting.

"What a Man wishes, he will also believe"

— Demosthenes

At first, when people disagree with us we assume they are ignorant ... that they lack information. So we try to convince them with information. If we show them that information and they still don't change their mind, we just think they're idiots.

In her book Being Wrong: Adventures in the Margin of Error, Kathryn Schulz explains:

... The first thing we usually do when someone disagrees with us is that we just assume they are ignorant. You know, they don't have access to the same information we do and when we generously share that information with them, they are going to see the light and come on over to our team.

When that doesn't work. When it turns out those people have all the same information and they still don't agree with us we move onto a second assumption. They're idiots ...

This approach of trying to convince people that we're right and they're wrong is flawed and rarely works. And it's not because people are idiots, most of them are not.

The Illusion of Explanatory Depth

In many cases, we are overconfident about what we think because we're familiar with the material. We think we know more than we actually do because it's available to us. In short, we convince ourselves that we understand how something works when we don't.

In a study about a decade ago, Yale professors Leonid Rozenblit and Frank Keil asked students to explain how simple things work, like a flushing toilet, a sewing machine, piano keys, a zipper, and a cylinder lock. It turns out, we're not nearly as smart as we think.

When knowledge is put to the test, our familiarity with things leads to an (*unwarranted*) overconfidence about how they work.

Discovering that we don't know as much as we think isn't as easy as it may seem. Testing our own knowledge sounds like a lot of work. And most of the time others won't test it either, however, when they do our knowledge doesn't often match our confidence. And this is the beginning of how we start to show others or even ourselves that our view of the world might need updating.

"The first principle is that you must not fool yourself, and you are the easiest person to fool."

— Richard Feynman

The Era of Fake Knowledge

It's never been easier to fake what you know: to both yourself and to others.

It's the conservation of energy. Why put in the effort to learn something if we can get by most of the time without learning it? Why read the entire document when you can just skim the executive summary and get away with it?

Our intellectual laziness, however, comes with a cost. The more we coast the harder it gets to discern the difference between what we think we know and what we actually know. We end up fooling ourselves.

(There are two quick ways you can test your own understanding of something. The first is called the Feynman Technique, and the second is by doing the work required to hold an opinion.)

How to Win an Argument

Recent research shows how the illusion of knowledge might help you convince people they are wrong.

When asked to give reasons for their view, people remain as confident of their positions as they were before giving reasons. This is how we often argue with others. A tennis match of reasons served out and returned from one side to the other. Only no one is listening to the other or even considering they might be wrong. The way to really change minds and soften stances is to ask people to explain why they held views.

(Interestingly this very similar to the technique used by former FBI hostage negotiator Chris Voss to soften people's stances. He simply asks them how am I supposed to do that?)

We often can't explain why we think what we do. And when asked to explain it we realize that we're not as knowledgeable as we thought. That's when we revise our confidence level down and become more open to the views of others.

If you want to win an argument, simply ask the person trying to convince you of something to explain *how* it would work.

Odds are they have not done the work required to hold an opinion. If they can explain why they are correct and how things would work, you'll learn something. If they can't you'll soften their views, perhaps nudging them ever so softly toward your views.

It is worth bearing in mind, however, that someone might do the same to you so make sure you can explain why you think what you do.

62. Warren Buffett on Scorecards, Investing, Friends, and the Family Motto

This website is named after a street located in Omaha, Nebraska. An amazing place, Omaha is famous for being the home of Warren Buffett, one of the world's richest men. The headquarters of Berkshire Hathaway — and his house — just happen to be on “Farnam Street.” The name of this website is an homage to both Buffett and his business partner Charlie Munger.

While Buffett is famous for his investing acumen, he's also full of sage wisdom on life and living.

In October 2009, while the housing crisis was still in full effect, his authorized biography *The Snowball: Warren Buffett and the Business of Life* hit the shelves.

Here are some of his lessons on life and investing.

Three Early Lessons in Investing

Having bought three shares of Cities Service Preferred at the age of 11, Buffett learned a valuable lesson. After the stock plunged from \$38.25 to \$27 a share. His sister Doris reminded him daily on the way to school that her stock was going down. Buffett felt “terribly” responsible. When the stock recovered he sold with a slight \$5 profit. Almost immediately after, Cities Service quickly soared to \$202 a share.

Warren learned three lessons and would call this episode one of the most important of his life. One lesson was not to overly fixate on what he had paid for a stock. The second was not to rush unthinkingly to grab a small profit. He learned these two lessons by brooding over the \$ 492 he would have made had he been more patient. It had taken five years of work, since he was six years old, to save the \$ 120 to buy this stock. Based on how much he currently made from selling golf balls or peddling popcorn and peanuts at the ballpark, he realized that it could take years to earn back the profit he had “lost.” He would never, never, never forget this mistake. And there was a third lesson, which was about investing other people's money. If he made a mistake, it might get somebody upset at him. So he didn't want to have responsibility for anyone else's money unless he was sure he could succeed.

The Scorecard

This is an important one to keep in mind. If we place too much emphasis on what the world thinks, we end up with an outer scorecard.

I feel like I'm on my back, and there's the Sistine Chapel, and I'm painting away. I like it when people say, 'Gee, that's a pretty good-looking painting.' But it's my painting, and when somebody says, 'Why don't you use more red instead of blue?' Good-bye. It's my painting. And I don't care what they sell it for. The painting itself will never be finished. That's one of the great things about it.

“The big question about how people behave is whether they've got an Inner Scorecard or an Outer Scorecard. It helps if you can be satisfied with an Inner Scorecard. I always pose it this way. I say: 'Lookit. Would you rather be the world's greatest lover, but have everyone think you're the world's worst lover? Or would you rather be the world's worst lover but have everyone think you're the world's greatest lover?' Now, that's an interesting question.

This has implications if you're a parent: What you put emphasis on matters.

If all the emphasis is on what the world's going to think about you, forgetting about how you really behave, you'll wind up with an Outer Scorecard.

Hang Around People Better Than You

After graduating from Columbia University, Buffett returned to Omaha to live with his parents. He spent part of that first summer fulfilling his obligation to the National Guard. While he wasn't a natural, it sure beat going off to fight in Korea. Part of his duties in the guard required him to attend training camp in La Crosse, Wisconsin, for a few weeks. That experience taught him an incredible lesson that he'd carry forward for the rest of his life.

“It's a very democratic organization. I mean, what you do outside doesn't mean much. To fit in, all you had to do was be willing to read comic books. About an hour after I got there, I

was reading comic books. Everybody else was reading comic books, why shouldn't I? My vocabulary shrank to about four words, and you can guess what they were.

"I learned that it pays to hang around with people better than you are, because you will float upward a little bit. And if you hang around with people that behave worse than you , pretty soon you'll start sliding down the pole. It just works that way."

The Buffett Family Motto

As simple as it is powerful.

"Spend less than you make" could, in fact, have been the Buffett family motto, if accompanied by its corollary, "Don't go into debt."

Why Buffett Wanted Money

Even when he was little h,e was always fixated on money. He wanted money. Why?

"It could make me independent. Then I could do what I wanted to do with my life. And the biggest thing I wanted to do was work for myself . I didn't want other people directing me. The idea of doing what I wanted to do every day was important to me."

Principles

In July of 1952, Susie Buffett, having been married only a few months to Warren, went to Chicago with her parents and new in-laws for the Republican convention. The convention was covered on television for the first time in history. Warren, who stayed in Omaha, watched eagerly — "struck by the power of this medium to magnify and influence events." The front-runner was Senator Robert Taft, known as "Mr. Integrity." He wanted three things: (1) small government; (2) pro-business; and (3) eradicate Communism. Taft's friend and Warren's father, Howard Buffett, was the head of his presidential campaign. Taft's main opponent was the moderate and popular war hero General Dwight D. Eisenhower. While it might have been the first convention covered by television it still lives in the history books as one of the most controversial Republican conventions. Eisenhower backers pushed through a controversial amendment to the rules that handed him the nomination on the first ballot. Taft and his supporters were, of course, outraged.

But Eisenhower soon made peace with them by promising to combat "creeping socialism." Taft insisted that his followers swallow their outrage and vote for Eisenhower for the sake of regaining the White House. The Republicans united behind him and his running mate, Richard Nixon; "I Like Ike" buttons sprouted everywhere. Everywhere, that is, except on Howard Buffett's chest. He broke with the party by refusing to endorse Eisenhower. This was an act of political suicide. His support within the party evaporated overnight. He was left standing on principle— alone. Warren recognized that his father had "painted himself into a corner." From his earliest childhood, Warren had always tried to avoid broken promises, burned bridges, and confrontation. Now Howard's struggles branded three principles even deeper into his son: that allies are essential; that commitments are so sacred that by nature they should be rare; and that grandstanding rarely gets anything done.

Still Curious?

While reading about Buffett won't make you as smart as he is, you might learn something in the process. Pick up a copy of *The Snowball: Warren Buffett and the Business of Life* and give it a shot.

63. The Uses Of Being Wrong

Confessions of wrongness are the exception not the rule.

Daniel Drezner, a professor of international politics at the Fletcher School of Law and Diplomacy at Tufts University, pointing to the difference between being wrong in a prediction and making an error, writes:

Error, even if committed unknowingly, suggests sloppiness. That carries a more serious stigma than making a prediction that fails to come true.

Social sciences, unlike physical and natural sciences, finds a shortage of high-quality data on which to make predictions.

How does Science Advance?

A theory may be scientific even if there is not a shred of evidence in its favour, and it may be pseudoscientific even if all the available evidence is in its favour. That is, the scientific or non-scientific character of a theory can be determined independently of the facts. A theory is 'scientific' if one is prepared to specify in advance a crucial experiment (or observation) which can falsify it, and it is pseudoscientific if one refuses to specify such a 'potential falsifier'. But if so, we do not demarcate scientific theories from pseudoscientific ones, but rather scientific methods from non-scientific method.

Karl Popper viewed the progression of science as falsification — that is science progresses by elimination of what doesn't work and hold. Popper's falsifiability criterion ignores the tenacity of scientific theories, even in the face of disconfirming evidence.

Scientists, like many of us, do not abandon a theory because the evidence may contradict it.

The wake of science is littered with discussions on anomalies and not refutations.

Another theory on scientific advancement, proposed by Thomas Kuhn, a distinguished American philosopher of science, argues that science proceeds with a series of revolutions with an almost religious conversion.

Imre Lakatos, a Hungarian philosopher of mathematics and science, wrote:

(The) history of science, of course, is full of accounts of how crucial experiments allegedly killed theories. But all such accounts are fabricated long after the theory has been abandoned.

Lakatos bridged the gap between Popper and Kuhn by addressing what they failed to solve.

The hallmark of empirical progress is not trivial verifications: Popper is right that there are millions of them. It is no success for Newtonian theory that stones, when dropped, fall towards the earth, no matter how often this is repeated. But, so-called 'refutations' are not the hallmark of empirical failure, as Popper has preached, since all programmes grow in a permanent ocean of anomalies. What really counts are dramatic, unexpected, stunning predictions: a few of them are enough to tilt the balance; where theory lags behind the facts, we are dealing with miserable degenerating research programmes.

Now, how do scientific revolutions come about? If we have two rival research programmes, and one is progressing while the other is degenerating, scientists tend to join the progressive programme. This is the rationale of scientific revolutions. But while it is a matter of intellectual honesty to keep the record public, it is not dishonest to stick to a degenerating programme and try to turn it into a progressive one.

As opposed to Popper the methodology of scientific research programmes does not offer instant rationality. One must treat budding programmes leniently: programmes may take decades before they get off the ground and become empirically progressive. Criticism is not a Popperian quick kill, by refutation. Important criticism is always constructive: there is no refutation without a better theory. Kuhn is wrong in thinking that scientific revolutions are sudden, irrational changes in vision. [The history of science refutes both Popper and Kuhn:] On close inspection both Popperian crucial experiments and Kuhnian revolutions

turn out to be myths: what normally happens is that progressive research programmes replace degenerating ones.

A lot of the falsification effort is devoted to proving others wrong and not ourselves. “It’s rare for academics, Drezner writes, to publicly disavow their own theories and hypotheses.”

Indeed, a common lament in the social sciences is that negative findings—i.e., empirical tests that fail to support an author’s initial hypothesis—are never published.

Why is it so hard for us to see when we are wrong?

It is not necessarily concern for one’s reputation. Even predictions that turn out to be wrong can be intellectually profitable—all social scientists love a good straw-man argument to pummel in a literature review. Bold theories get cited a lot, regardless of whether they are right.

Part of the reason is simple psychology; we all like being right much more than being wrong.

As Kathryn Schulz observes in *Being Wrong*, “the thrill of being right is undeniable, universal, and (perhaps most oddly) almost entirely indiscriminating It’s more important to bet on the right foreign policy than the right racehorse, but we are perfectly capable of gloating over either one.”

As we create arguments and gather supporting evidence (while discarding evidence that does not fit) we increasingly persuade ourselves that we are right. We gain confidence and try to sway the opinions of others.

There are benefits to being wrong.

Schulz argues that “the capacity to err is crucial to human cognition. Far from being a moral flaw, it is inextricable from some of our most humane and honorable qualities: empathy, optimism, imagination, conviction, and courage. And far from being a mark of indifference or intolerance, wrongness is a vital part of how we learn and change.”

Drezner argues that some of the tools of the information age give us hope that we might become increasingly likely to admit being wrong.

Blogging and tweeting encourages the airing of contingent and tentative arguments as events play out in real time. As a result, far less stigma attaches to admitting that one got it wrong in a blog post than in peer-reviewed research. Indeed, there appears to be almost no professional penalty for being wrong in the realm of political punditry. Regardless of how often pundits make mistakes in their predictions, they are invited back again to pontificate more.

As someone who has blogged for more than a decade, I’ve been wrong an awful lot, and I’ve grown somewhat more comfortable with the feeling. I don’t want to make mistakes, of course. But if I tweet or blog my half-formed supposition, and it then turns out to be wrong, I get more intrigued about why I was wrong. That kind of empirical and theoretical investigation seems more interesting than doubling down on my initial opinion. Younger scholars, weaned on the Internet, more comfortable with the push and pull of debate on social media, may well feel similarly.

64. The History of Cognitive Overload

The Organized Mind: Thinking Straight in the Age of Information Overload, a book by Daniel Levitin, has an interesting section on cognitive overload.

Each day we are confronted with hundreds, probably thousands of decisions. Most of which are insignificant or unimportant or both. Do we really need a whole aisle for toothpaste?

In response to all of these decisions, most of us adopt a strategy of *satisficing*, a term coined by Nobel Prize winner Herbert Simon to describe something that is perhaps not the best but good enough. For things that don't matter, this is a good approach. You don't know which pizza place is the best but you know which ones are good enough.

Satisficing is one of the foundations of productive human behavior; it prevails when we don't waste time on decisions that don't matter, or more accurately, when we don't waste time trying to find improvements that are not going to make a significant difference in our happiness or satisfaction.

All of us, Levitin argues, engage in satisficing every time we clean our homes.

If we got down on the floor with a toothbrush every day to clean the grout, if we scrubbed the windows and walls every single day, the house would be spotless. But few of us go to this much trouble even on a weekly basis (and when we do, we're likely to be labeled obsessive-compulsive). For most of us, we clean our houses until they are clean enough, reaching a kind of equilibrium between effort and benefit. It is this cost-benefits analysis that is at the heart of satisficing.

The easiest way to be happy is to want what you already have. "Happy people engage in satisficing all the time, even if they don't know it."

Satisficing is a tool that allows you not to waste time on things that don't really matter. Who cares if you pick Colgate or Crest? For other decisions, "the old-fashioned pursuit of excellence remains the right strategy."

We now spend an unusual amount of time and energy ignoring and filtering. Consider the supermarket.

In 1976, the average supermarket stocked 9,000 unique products; today that number has ballooned to 40,000 of them, yet the average person gets 80%– 85% of their needs in only 150 different supermarket items. That means that we need to ignore 39,850 items in the store.

This comes with a cost.

Neuroscientists have discovered that unproductivity and loss of drive can result from decision overload. Although most of us have no trouble ranking the importance of decisions if asked to do so, our brains don't automatically do this.

We have a limited number of decisions. After all, there are only so many we can make in a day without compromising quality. Once we've hit that limit it doesn't matter how important they are.

The decision-making network in our brain doesn't prioritize.

Our world has exploded. Information is abundant. I didn't think we could process it all but Levitin argues that we can, at a cost.

We can have trouble separating the trivial from the important, and all this information processing makes us tired. Neurons are living cells with a metabolism; they need oxygen and glucose to survive and when they've been working hard, we experience fatigue. Every status update you read on Facebook, every tweet or text message you get from a friend, is competing for resources in your brain with important things like whether to put your savings in stocks or bonds, where you left your passport, or how best to reconcile with a close friend you just had an argument with.

The processing capacity of the conscious mind has been estimated at 120 bits per second. That bandwidth, or window, is the speed limit for the traffic of information we can pay conscious attention to at any one time. While a great deal occurs below the threshold of

our awareness, and this has an impact on how we feel and what our life is going to be like, in order for something to become encoded as part of your experience, you need to have paid conscious attention to it.

What does this mean?

In order to understand one person speaking to us, we need to process 60 bits of information per second. With a processing limit of 120 bits per second, this means you can barely understand two people talking to you at the same time. Under most circumstances, you will not be able to understand three people talking at the same time. ...

With such attentional restrictions, it's clear why many of us feel overwhelmed by managing some of the most basic aspects of life. Part of the reason is that our brains evolved to help us deal with life during the hunter-gatherer phase of human history, a time when we might encounter no more than a thousand people across the entire span of our lifetime. Walking around midtown Manhattan, you'll pass that number of people in half an hour.

Attention is the most essential mental resource for any organism. It determines which aspects of the environment we deal with, and most of the time, various automatic, subconscious processes make the correct choice about what gets passed through to our conscious awareness. For this to happen, millions of neurons are constantly monitoring the environment to select the most important things for us to focus on. These neurons are collectively the attentional filter. They work largely in the background, outside of our conscious awareness. This is why most of the perceptual detritus of our daily lives doesn't register, or why, when you've been driving on the freeway for several hours at a stretch, you don't remember much of the scenery that has whizzed by: Your attentional system "protects" you from registering it because it isn't deemed important. This unconscious filter follows certain principles about what it will let through to your conscious awareness.

The attentional filter is one of evolution's greatest achievements. In nonhumans, it ensures that they don't get distracted by irrelevancies. Squirrels are interested in nuts and predators, and not much else. Dogs, whose olfactory sense is one million times more sensitive than ours, use smell to gather information about the world more than they use sound, and their attentional filter has evolved to make that so. If you've ever tried to call your dog while he is smelling something interesting, you know that it is very difficult to grab his attention with sound—smell trumps sound in the dog brain. No one has yet worked out all of the hierarchies and trumping factors in the human attentional filter, but we've learned a great deal about it. When our protohuman ancestors left the cover of the trees to seek new sources of food, they simultaneously opened up a vast range of new possibilities for nourishment and exposed themselves to a wide range of new predators. Being alert and vigilant to threatening sounds and visual cues is what allowed them to survive; this meant allowing an increasing amount of information through the attentional filter.

Levitin points out an interesting fact on how highly successful people (HSP) differ from the rest of us when it comes to attentional filters.

Successful people—or people who can afford it—employ layers of people whose job it is to narrow the attentional filter. That is, corporate heads, political leaders, spoiled movie stars, and others whose time and attention are especially valuable have a staff of people around them who are effectively extensions of their own brains, replicating and refining the functions of the prefrontal cortex's attentional filter.

These highly successful persons have many of the daily distractions of life handled for them, allowing them to devote all of their attention to whatever is immediately before them. They seem to live completely in the moment. Their staff handle correspondence, make appointments, interrupt those appointments when a more important one is waiting, and help to plan their days for maximum efficiency (including naps!). Their bills are paid on time, their car is serviced when required, they're given reminders of projects due, and their assistants send suitable gifts to the HSP's loved ones on birthdays and anniversaries. Their ultimate prize if it all works? A Zen-like focus.

Levitin argues that if we organize our minds and our lives “following the new neuroscience of attention and memory, we can all deal with the world in ways that provide the sense of freedom that these highly successful people enjoy.”

To do that, however, we need to understand the architecture of our attentional system. “To better organize our mind, we need to know how it has organized itself.”

Change and importance are two crucial principles used by our attentional filter.

The brain's change detector is at work all the time, whether you know it or not. If a close friend or relative calls on the phone, you might detect that her voice sounds different and ask if she's congested or sick with the flu. When your brain detects the change, this information is sent to your consciousness, but your brain doesn't explicitly send a message when there is no change. If your friend calls and her voice sounds normal, you don't immediately think, “Oh, her voice is the same as always.” Again, this is the attentional filter doing its job, detecting change, not constancy.

Importance can also filter information. But it's not objective or absolute importance but something personal and relevant to you.

If you're driving, a billboard for your favorite music group might catch your eye (really, we should say catch your mind) while other billboards go ignored. If you're in a crowded room, at a party for instance, certain words to which you attach high importance might suddenly catch your attention, even if spoken from across the room. If someone says “fire” or “sex” or your own name, you'll find that you're suddenly following a conversation far away from where you're standing, with no awareness of what those people were talking about before your attention was captured.

The attentional filter lets us live on autopilot most of the time coming out of it only when we need to. In so doing, we “do not register the complexities, nuances, and often the beauty of what is right in front of us.”

A great number of failures of attention occur because we are not using these two principles to our advantage.

Simply put, attention is limited.

A critical point that bears repeating is that attention is a limited-capacity resource— there are definite limits to the number of things we can attend to at once. We see this in everyday activities. If you're driving, under most circumstances, you can play the radio or carry on a conversation with someone else in the car. But if you're looking for a particular street to turn onto, you instinctively turn down the radio or ask your friend to hang on for a moment, to stop talking. This is because you've reached the limits of your attention in trying to do these three things. The limits show up whenever we try to do too many things at once.

Our brain hides things from us.

The human brain has evolved to hide from us those things we are not paying attention to. In other words, we often have a cognitive blind spot: We don't know what we're missing because our brain can completely ignore things that are not its priority at the moment—even if they are right in front of our eyes. Cognitive psychologists have called this blind spot various names, including inattentive blindness.

A lot of instances of losing things like car keys, passports, money, receipts, and so on occur because our attentional systems are overloaded and they simply can't keep track of everything. The average American owns thousands of times more possessions than the average hunter-gatherer. In a real biological sense, we have more things to keep track of than our brains were designed to handle. Even towering intellectuals such as Kant and Wordsworth complained of information excess and sheer mental exhaustion induced by too much sensory input or mental overload.

But we need not fear this cognitive overload, Levitin argues. “More than ever, effective external systems are available for organizing, categorizing, and keeping track of things.”

Information Overload, Then and Now

We've been around a long time. For most of that time we didn't do much of anything other than "procreate and survive." Then we discovered farming and irrigation and gave up our fairly nomadic lifestyle. Farming allowed us to specialize. I could grow potatoes and you could grow tomatoes and we could trade. This created a dependency on each other and markets for trading. All of this trading, in turn required an accounting system to keep tabs on inventory and trades. This was the birthplace of writing.

With the growth of trade, cities, and writing, people soon discovered architecture, government, and the other refinements of being that collectively add up to what we think of as civilization. The appearance of writing some 5,000 years ago was not met with unbridled enthusiasm; many contemporaries saw it as technology gone too far, a demonic invention that would rot the mind and needed to be stopped. Then, as now, printed words were promiscuous—it was impossible to control where they went or who would receive them, and they could circulate easily without the author's knowledge or control. Lacking the opportunity to hear information directly from a speaker's mouth, the antiwriting contingent complained that it would be impossible to verify the accuracy of the writer's claims, or to ask follow-up questions. Plato was among those who voiced these fears; his King Thamus decried that the dependence on written words would "weaken men's characters and create forgetfulness in their souls." Such externalization of facts and stories meant people would no longer need to mentally retain large quantities of information themselves and would come to rely on stories and facts as conveyed, in written form, by others. Thamus, king of Egypt, argued that the written word would infect the Egyptian people with fake knowledge. The Greek poet Callimachus said books are "a great evil." The Roman philosopher Seneca the Younger (tutor to Nero) complained that his peers were wasting time and money accumulating too many books, admonishing that "the abundance of books is a distraction." Instead, Seneca recommended focusing on a limited number of good books, to be read thoroughly and repeatedly. Too much information could be harmful to your mental health.

Cue the printing press, which allowed for the rapid copying of books. This further complicated intellectual life.

The printing press was introduced in the mid 1400s, allowing for the more rapid proliferation of writing, replacing laborious (and error-prone) hand copying. Yet again, many complained that intellectual life as we knew it was done for. Erasmus, in 1525, went on a tirade against the "swarms of new books," which he considered a serious impediment to learning. He blamed printers whose profit motive sought to fill the world with books that were "foolish, ignorant, malignant, libelous, mad, impious and subversive." Leibniz complained about "that horrible mass of books that keeps on growing" and that would ultimately end in nothing less than a "return to barbarism." Descartes famously recommended ignoring the accumulated stock of texts and instead relying on one's own observations. Presaging what many say today, Descartes complained that "even if all knowledge could be found in books, where it is mixed in with so many useless things and confusingly heaped in such large volumes, it would take longer to read those books than we have to live in this life and more effort to select the useful things than to find them oneself."

A steady flow of complaints about the proliferation of books reverberated into the late 1600s. Intellectuals warned that people would stop talking to each other, burying themselves in books, polluting their minds with useless, fatuous ideas.

There is an argument that this generation is at the same crossroads — our Gutenberg moment.

iPhones and iPads, email, and Twitter are the new revolution.

Each was decried as an addiction, an unnecessary distraction, a sign of weak character, feeding an inability to engage with real people and the real-time exchange of ideas.

The industrial revolution brought along a rapid rise in discovery and advancement. Scientific information increased at a staggering clip.

Today, someone with a PhD in biology can't even know all that is known about the nervous system of the squid! Google Scholar reports 30,000 research articles on that topic, with the number increasing exponentially. By the time you read this, the number will have increased by at least 3,000. The amount of scientific information we've discovered in the last twenty years is more than all the discoveries up to that point, from the beginning of language.

This is taxing all of us as we filter what we need to know from what we don't. This ties in nicely with Tyler Cowen's argument that the future of work is changing and we will need to add value to computers.

To cope with information overload we create to-do lists and email ourselves reminders. I have lists of lists. Right now there are over 800 unread emails in my inbox. Many of these are reminders to myself to look into something or to do something, links that I need to go back and read, or books I want to add to my wishlist. I see those emails and think, yes I want to do that but not right now. So they sit in my inbox. Occasionally I'll create a to-do list, which starts off with the best intentions and rapidly becomes a brain dump. Eventually I remember the 18 minute plan for managing your day and I re-focus, scheduling time for the most important things. No matter what I do I always feel like I'm on the border between organized and chaos.

A large part of this feeling of being overwhelmed can be traced back to our evolutionarily outdated attentional system. I mentioned earlier the two principles of the attentional filter: change and importance. There is a third principle of attention— not specific to the attentional filter— that is relevant now more than ever. It has to do with the difficulty of attentional switching. We can state the principle this way: Switching attention comes with a high cost.

Our brains evolved to focus on one thing at a time. This enabled our ancestors to hunt animals, to create and fashion tools, to protect their clan from predators and invading neighbors. The attentional filter evolved to help us to stay on task, letting through only information that was important enough to deserve disrupting our train of thought. But a funny thing happened on the way to the twenty-first century: The plethora of information and the technologies that serve it changed the way we use our brains. Multitasking is the enemy of a focused attentional system. Increasingly, we demand that our attentional system try to focus on several things at once, something that it was not evolved to do. We talk on the phone while we're driving, listening to the radio, looking for a parking place, planning our mom's birthday party, trying to avoid the road construction signs, and thinking about what's for lunch. We can't truly think about or attend to all these things at once, so our brains flit from one to the other, each time with a neurobiological switching cost. The system does not function well that way. Once on a task, our brains function best if we stick to that task.

When you pay attention to something it means you don't see something else. David Foster Wallace hit upon this in his speech, The Truth With A Whole Lot Of Rhetorical Bullshit Pared Away. He said:

Learning how to think really means learning how to exercise some control over how and what you think. It means being conscious and aware enough to choose what you pay attention to and to choose how you construct meaning from experience. Because if you cannot exercise this kind of choice in adult life, you will be totally hosed. Think of the old cliché about the mind being an excellent servant but a terrible master. This, like many clichés, so lame and unexciting on the surface, actually expresses a great and terrible truth.

And Winifred Gallagher, author of the book Rapt: Attention and the Focused Life, wrote:

That your experience largely depends on the material objects and mental subjects that you choose to pay attention to or ignore is not an imaginative notion, but a physiological fact. When you focus on a stop sign or a sonnet, a waft of perfume or a stock-market tip, your brain registers that “target,” which enables it to affect your behavior. In contrast, the things that you don’t attend to in a sense don’t exist, at least for you.

All day long, you are selectively paying attention to something, and much more often than you may suspect, you can take charge of this process to good effect. Indeed, your ability to focus on this and suppress that is the key to controlling your experience and, ultimately, your well-being.

When you walk into the front door of your house after a long day of work to screaming kids and a ringing phone you’re not thinking about where you left your car keys.

Attention is created by networks of neurons in the prefrontal cortex (just behind your forehead) that are sensitive only to dopamine. When dopamine is released, it unlocks them, like a key in your front door, and they start firing tiny electrical impulses that stimulate other neurons in their network. But what causes that initial release of dopamine? Typically, one of two different triggers:

1. Something can grab your attention automatically, usually something that is salient to your survival, with evolutionary origins. This vigilance system incorporating the attentional filter is always at work, even when you’re asleep, monitoring the environment for important events. This can be a loud sound or bright light (the startle reflex), something moving quickly (that might indicate a predator), a beverage when you’re thirsty, or an attractively shaped potential sexual partner.

2. You effectively will yourself to focus only on that which is relevant to a search or scan of the environment. This deliberate filtering has been shown in the laboratory to actually change the sensitivity of neurons in the brain. If you’re trying to find your lost daughter at the state fair, your visual system reconfigures to look only for things of about her height, hair color, and body build, filtering everything else out. Simultaneously, your auditory system retunes itself to hear only frequencies in that band where her voice registers. You could call it the Where’s Waldo? filtering network.

It all comes back to Waldo.

If it has red in it, our red-sensitive neurons are involved in the imagining. They then automatically tune themselves, and inhibit other neurons (the ones for the colors you’re not interested in) to facilitate the search. Where’s Waldo? trains children to set and exercise their visual attentional filters to locate increasingly subtle cues in the environment, much as our ancestors might have trained their children to track animals through the forest, starting with easy-to-see and easy-to-differentiate animals and working up to camouflaging animals that are more difficult to pick out from the surrounding environment. The system also works for auditory filtering— if we are expecting a particular pitch or timbre in a sound, our auditory neurons become selectively tuned to those characteristics.

When we willfully retune sensory neurons in this way, our brains engage in top-down processing, originating in a higher, more advanced part of the brain than sensory processing.

But if we have an effective attention filter, why do we find it so hard to filter out distractions? Cue technology.

For one thing, we’re doing more work than ever before. The promise of a computerized society, we were told, was that it would relegate to machines all of the repetitive drudgery of work, allowing us humans to pursue loftier purposes and to have more leisure time. It didn’t work out this way. Instead of more time, most of us have less. Companies large and small have off-loaded work onto the backs of consumers. Things that used to be done for us, as part of the value-added service of working with a company, we are now expected to do ourselves. With air travel, we’re now expected to complete our own reservations and check-in, jobs that used to be done by airline employees or travel agents. At the grocery

store, we're expected to bag our own groceries and, in some supermarkets, to scan our own purchases. We pump our own gas at filling stations. Telephone operators used to look up numbers for us. Some companies no longer send out bills for their services— we're expected to log in to their website, access our account, retrieve our bill, and initiate an electronic payment; in effect, do the job of the company for them. Collectively, this is known as shadow work— it represents a kind of parallel, shadow economy in which a lot of the service we expect from companies has been transferred to the customer. Each of us is doing the work of others and not getting paid for it. It is responsible for taking away a great deal of the leisure time we thought we would all have in the twenty-first century. Beyond doing more work, we are dealing with more changes in information technology than our parents did, and more as adults than we did as children. The average American replaces her cell phone every two years, and that often means learning new software, new buttons, new menus. We change our computer operating systems every three years, and that requires learning new icons and procedures, and learning new locations for old menu items.

It's not a coincidence that highly successful people tend to offload these tasks to others, allowing them to focus.

As knowledge becomes more available— and decentralized through the Internet— the notions of accuracy and authoritativeness have become clouded. Conflicting viewpoints are more readily available than ever, and in many cases they are disseminated by people who have no regard for facts or truth. Many of us find we don't know whom to believe, what is true, what has been modified, and what has been vetted.

[...]

My teacher, the Stanford cognitive psychologist Amos Tversky, encapsulates this in "the Volvo story." A colleague was shopping for a new car and had done a great deal of research. Consumer Reports showed through independent tests that Volvos were among the best built and most reliable cars in their class. Customer satisfaction surveys showed that Volvo owners were far happier with their purchase after several years. The surveys were based on tens of thousands of customers. The sheer number of people polled meant that any anomaly— like a specific vehicle that was either exceptionally good or exceptionally bad— would be drowned out by all the other reports. In other words, a survey such as this has statistical and scientific legitimacy and should be weighted accordingly when one makes a decision. It represents a stable summary of the average experience, and the most likely best guess as to what your own experience will be (if you've got nothing else to go on, your best guess is that your experience will be most like the average).

Amos ran into his colleague at a party and asked him how his automobile purchase was going. The colleague had decided against the Volvo in favor of a different, lower-rated car. Amos asked him what made him change his mind after all that research pointed to the Volvo. Was it that he didn't like the price? The color options? The styling? No, it was none of those reasons, the colleague said. Instead, the colleague said, he found out that his brother-in-law had owned a Volvo and that it was always in the shop.

From a strictly logical point of view, the colleague is being irrational. The brother-in-law's bad Volvo experience is a single data point swamped by tens of thousands of good experiences— it's an unusual outlier. But we are social creatures. We are easily swayed by first-person stories and vivid accounts of a single experience. Although this is statistically wrong and we should learn to overcome the bias, most of us don't. Advertisers know this, and this is why we see so many first-person testimonial advertisements on TV. "I lost twenty pounds in two weeks by eating this new yogurt— and it was delicious, too!" Or "I had a headache that wouldn't go away. I was barking at the dog and snapping at my loved ones. Then I took this new medication and I was back to my normal self." Our brains focus on vivid, social accounts more than dry, boring, statistical accounts.

So not only does knowledge become easier to access than ever before (frictionless) but as it becomes more available our brains need to cope with it, which they do by magnifying our pre-existing cognitive biases.

In Roger Shepard's version of the famous "Ponzo illusion," the monster at the top seems larger than the one at the bottom, but a ruler will show that they're the same size. In the Ebbinghaus illusion below it, the white circle on the left seems larger than the white circle on the right, but they're the same size. We say that our eyes are playing tricks on us, but in fact, our eyes aren't playing tricks on us, our brain is. The visual system uses heuristics or shortcuts to piece together an understanding of the world, and it sometimes gets things wrong.

We are prone to cognitive illusions when we make decisions. The same type of shortcuts are at play.

65. Seymour Schulich on Deals, Business, Decisions and Life

Seymour Schulich, one of Canada's most successful businessmen and author of Get Smarter: Life and Business Lessons offers some indispensable business wisdom.

1. *Business is a means to an end not an end in itself. Nobody on his or her deathbed says, "I wish I had spent more time in the office."*
2. *Never quit a job unless you have another job. My father taught me this great truth. You are perceived as more valuable if you are working than if you're unemployed. You may feel staying employed doesn't give you the time or latitude to seek a better job. This is a dangerous delusion—don't succumb to it.*
3. *Always ask the question "If this decision is wrong, is it going to be painful or fatal?" Company builders and business leaders keep away from "bet the company" investments.*
4. *Keep away from advisors/consultants. If they knew how to make money, they would. These folks are like the fellow who knows a thousand ways to make love but doesn't know any women.*
5. *The best test of a deal's true attraction is to ask your partners, employees, directors, family, and so on, "Would you put your own money in this deal?" It's amazing how often the answer to this question is, "No! This is good for the company, but I'll take a pass." These deals are invariably losers.*
6. *Always have at least two people from your side present at any negotiating or deal-making sessions. This gives you time to think, plus an ally with whom to compare perceptions.*
7. *Never confront or threaten people or institutions who have more power than you. Examples: police, customs agents, the sec, Ontario Securities Commission, tax agents of the government, or politicians.*
8. *In dealing with the media, never forget to qualify your statements with "not for attribution" and "off the record" where appropriate. Journalists value their contacts and will usually respect a source's desires.*
9. *In negotiations, always try to get the other party to name its asking price. It may often be far lower than your maximum offer. If the other party won't name a price, start very low. You can always go up.*
10. *Almost everything in life is easier to get into than get out of.*
11. *Never bid against yourself. Only raise your bid to top a real counter bid, not an imaginary one.*

66. The Munger Operating System: How to Live a Life That Really Works

In 2007, Charlie Munger gave the commencement address at USC Law School, opening his speech by saying, *“Well, no doubt many of you are wondering why the speaker is so old. Well, the answer is obvious: He hasn’t died yet.”*

Fortunately for us, Munger has kept on ticking. The commencement speech is an excellent response to the Big Question: *How do we live a life that really works?* It has so many of Munger’s core ideas that we think the speech represents the Munger Operating System for life.

To get what you want, deserve what you want. Trust, success, and admiration are earned. *It’s such a simple idea. It’s the golden rule so to speak: You want to deliver to the world what you would buy if you were on the other end. There is no ethos, in my opinion, that is better for any lawyer or any other person to have. By and large the people who have this ethos win in life and they don’t win just money, not just honors. They win the respect, the deserved trust of the people they deal with, and there is huge pleasure in life to be obtained from getting deserved trust.*

Learn to love and admire the right people, alive or dead.

A second idea that I got very early was that there is no love that’s so right as admiration-based love, and that love should include the instructive dead. Somehow, I got that idea and I lived with it all my life; and it’s been very, very useful to me.

Acquiring wisdom is a moral duty as well as a practical one.

And there’s a corollary to that proposition which is very important. It means that you’re hooked for lifetime learning, and without lifetime learning you people are not going to do very well. You are not going to get very far in life based on what you already know. You’re going to advance in life by what you’re going to learn after you leave here...if civilization can progress only when it invents the method of invention, you can progress only when you learn the method of learning.

Attain fluency on the big multidisciplinary ideas of the world and use them regularly.

What I noted since the really big ideas carry 95% of the freight, it wasn’t at all hard for me to pick up all the big ideas from all the big disciplines and make them a standard part of my mental routines. Once you have the ideas, of course, they are no good if you don’t practice — if you don’t practice you lose it.

So I went through life constantly practicing this model of the multidisciplinary approach. Well, I can't tell you what that's done for me. It's made life more fun, it's made me more constructive, it's made me more helpful to others, it's made me enormously rich, you name it, that attitude really helps.

Now there are dangers there, because it works so well, that if you do it, you will frequently find you are sitting in the presence of some other expert, maybe even an expert that's superior to you, supervising you. And you will know more than he does about his own specialty, a lot more. You will see the correct answer when he's missed it.

[...]

It doesn't help you just to know them enough just so you can give them back on an exam and get an A. You have to learn these things in such a way that they're in a mental latticework in your head and you automatically use them for the rest of your life.

Learn to think through problems backwards as well as forward.

The way complex adaptive systems work and the way mental constructs work, problems frequently get easier and I would even say usually are easier to solve if you turn around in reverse.

In other words if you want to help India, the question you should ask is not "how can I help India?", you think "what's doing the worst damage in India? What would automatically do the worst damage and how do I avoid it?" You'd think they are logically the same thing, but they're not. Those of you who have mastered algebra know that inversion frequently will solve problems which nothing else will solve. And in life, unless you're more gifted than Einstein, inversion will help you solve problems that you can't solve in other ways.

Be reliable. Unreliability can cancel out the other virtues.

If you're unreliable it doesn't matter what your virtues are, you're going to crater immediately. So doing what you have faithfully engaged to do should be an automatic part of your conduct. You want to avoid sloth and unreliability.

Avoid intense ideologies. Always consider the other side as carefully as your own.

Another thing I think should be avoided is extremely intense ideology, because it cabbages up one's mind. You've seen that. You see a lot of it on TV, you know preachers for instance, they've all got different ideas about theology and a lot of them have minds that are made of cabbage.

But that can happen with political ideology. And if you're young it's easy to drift into loyalties and when you announce that you're a loyal member and you start shouting the orthodox ideology out what you're doing is pounding it in, pounding it in, and you're gradually ruining your mind. So you want to be very careful with this ideology. It's a big danger.

In my mind I have a little example I use whenever I think about ideology, and it's these Scandinavian canoeists who succeeded in taming all the rapids of Scandinavia and they thought they would tackle the whirlpools in the Grand Rapids here in the United States. The death rate was 100%. A big whirlpool is not something you want to go into and I think the same is true about a really deep ideology.

I have what I call an iron prescription that helps me keep sane when I naturally drift toward preferring one ideology over another. And that is I say "I'm not entitled to have an opinion on this subject unless I can state the arguments against my position better than the people do who are supporting it. I think that only when I reach that stage am I qualified to speak." Now you can say that's too much of an iron discipline..it's not too much of an iron discipline. It's not even that hard to do.

Get rid of self-serving bias, envy, resentment, and self-pity.

Generally speaking, envy, resentment, revenge and self pity are disastrous modes of thought. Self-pity gets pretty close to paranoia, and paranoia is one of the very hardest things to reverse. You do not want to drift into self-pity.

I have a friend who carried a big stack of index cards about this thick, and when somebody would make a comment that reflected self pity, he would take out one of the cards, take the top one off the stack and hand it to the person, and the card said, "Your story has touched my heart, never have I heard of anyone with as many misfortunes as you". Well, you can say that's waggery, but I suggest that every time you find you're drifting into self pity, I don't care what the cause — your child could be dying of cancer — self-pity is not going to improve the situation. Just give yourself one of those cards.

It's a ridiculous way to behave, and when you avoid it you get a great advantage over everybody else, almost everybody else, because self-pity is a standard condition and yet you can train yourself out of it.

And of course self-serving bias, you want to get that out of yourself; thinking that what's good for you is good for the wider civilization and rationalizing all these ridiculous conclusions based on the subconscious tendency to serve one's self.

At the same time, allow for the self-serving bias in others who haven't removed it.

You also have to allow for the self serving bias of everybody else, because most people are not going to remove it all that successfully, the human condition being what it is. If you don't allow for self serving bias in your conduct, again you're a fool.

I watched the brilliant Harvard Law School trained general counsel of Salomon lose his career, and what he did was when the CEO became aware that some underling had done something wrong, the general counsel said, "Gee, we don't have any legal duty to report this but I think it's what we should do it's our moral duty."

Of course, the general counsel was totally correct but of course it didn't work; it was a very unpleasant thing for the CEO to do and he put it off and put it off and of course everything eroded into a major scandal and down went the CEO and the general counsel with him.

The correct answer in situations like that was given by Ben Franklin, he said, "If you want to persuade, appeal to interest not to reason." The self serving bias is so extreme. If the general counsel had said, "Look this is going to erupt, it's something that will destroy you, take away your money, take away your status...it's a perfect disaster," it would have worked!

Avoid being part of a system with perverse incentives.

Incentives are too powerful a controller of human cognition and human behavior, and one of the things you are going to find in some modern law firms is billable hour quotas. I could not have lived under a billable hour quota of 2,400 hours a year. That would have caused serious problems for me — I wouldn't have done it and I don't have a solution for you for that. You'll have to figure it out for yourself but it's a significant problem.

Work with and under people you admire, and avoid the inverse when at all possible.

And that requires some talent. The way I solved that is, I figured out the people I did admire and I maneuvered cleverly without criticizing anybody, so I was working entirely under people I admired. And a lot of law firms will permit that if you're shrewd enough to work it out. And your outcome in life will be way more satisfactory and way better if you work under people you really admire. The alternative is not a good idea.

Learn to maintain your objectivity, especially when it's hardest.

Well we all remember that Darwin paid special attention to disconfirming evidence particularly when it disconfirmed something he believed and loved. Well, objectivity maintenance routines are totally required in life if you're going to be a correct thinker. And there we're talking about Darwin's attitude, his special attention to disconfirming evidence, and also to checklist routines. Checklist routines avoid a lot of errors. You should have all this elementary wisdom and then you should go through and have a checklist in order to use it. There is no other procedure that will work as well.

Concentrate experience and power into the hands of the right people — the wise learning machines.

I think the game of life in many respects is getting a lot of practice into the hands of the people that have the most aptitude to learn and the most tendency to be learning machines. And if you want the very highest reaches of human civilization that's where you have to go.

You do not want to choose a brain surgeon for your child among fifty applicants all of them just take turns during the procedure. You don't want your airplanes designed that way. You don't want your Berkshire Hathaways run that way. You want to get the power into the right people.

You'll be most successful where you're most intensely interested.

Another thing that I found is an intense interest of the subject is indispensable if you are really going to excel. I could force myself to be fairly good in a lot of things, but I couldn't be really good in anything where I didn't have an intense interest. So to some extent, you're going to have to follow me. If at all feasible you want to drift into doing something in which you really have a natural interest.

Learn the all-important concept of assiduity: Sit down and do it until it's done.

Two partners that I chose for one little phase of my life had the following rule: They created a little design/build construction team, and they sat down and said, two-man partnership, divide everything equally, here's the rule; "Whenever we're behind in our commitments to other people, we will both work 14 hours a day until we're caught up."

Well, needless to say, that firm didn't fail. The people died rich. It's such a simple idea.

Use setbacks in life as an opportunity to become a bigger and better person. Don't wallow.

Another thing of course is life will have terrible blows, horrible blows, unfair blows, doesn't matter. And some people recover and others don't. And there I think the attitude of Epictetus is the best. He thought that every mischance in life was an opportunity to behave well, every mischance in life was an opportunity to learn something, and your duty was not to be submerged in self-pity but to utilize the terrible blow in a constructive fashion. That is a very good idea.

The highest reach of civilization is a seamless system of trust among all parties concerned.

The last idea that I want to give you as you go out into a profession that frequently puts a lot of procedure and a lot of precautions and a lot of mumbo jumbo into what it does, this is not the highest form which civilization can reach. The highest form which civilization can reach is a seamless web of deserved trust. Not much procedure, just totally reliable people correctly trusting one another. That's the way an operating room works at the Mayo Clinic. If a bunch of lawyers were to introduce a lot of process, the patients would all die. So never forget when you're a lawyer that you may be rewarded for selling this stuff but you don't have to buy it. In your own life what you want is a seamless web of deserved trust. And if your proposed marriage contract has 47 pages, my suggestion is do not enter.

67. Alignment: The Key to Success Nobody Ever Taught You

I spend a lot of time thinking about this simple idea: The person who aligns themselves with the general principles of the world goes further and faster than the person who doesn't.

What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson.

— Joseph Tussman

The way to align yourself with the world is to take simple ideas seriously.

Consider compounding.

We know that spending less than we make, investing the difference in index funds, and waiting for a long time creates financial independence. Yet how many people follow this principle? Not many. Most of us know what works but fail to align ourselves with it.

Compounding applies to relationships too. Not just with your partner, but with your colleagues, friends, and even your customers. For relationships to compound, they must be win-win. But how many people take a consistent win-win approach? Not many. Again, we know what works, but fail to align ourselves with it.

Outcome over Ego

Here's the trick to seeing things differently: put your energy into *being* right, not *feeling* right. While that sounds simple, it's far from easy.

If you want to be right, you have to change your mind. When the evidence indicates the approach isn't working, change the approach. This is easy with something like math, where the answers are black and white, but harder with more subjective things.

Often the hardest things to change our minds about are the things that require us to understand that just because we can't see the results immediately doesn't mean they are not moving us closer or further from the outcome we want. For instance, eating a full pizza once won't make you unhealthy, but repeating that choice daily for years certainly will.

Feeling right, on the other hand, often requires you to believe you are an exception. You know the path to financial independence, but that takes too long. It's boring. Instead, you'd rather try the latest incarnation of a get-rich-quicker scheme that promises the outcome sooner. When it inevitably fails to produce the desired results, rather than tell yourself you made a mistake you chalk it up to the world not working as it should. It's as if that little voice in your head says, "You're not wrong; the world is."

Most of us would rather bargain with how the world works than accept how it does work, cooperate with it, and move forward. This happens in a lot of areas of life. Consider the general concept of health.

A lot of people think they don't have to take care of their health. They get too little sleep. They drink too much. They eat incredible amounts of processed food. They get little to no exercise. While they know health is important, at some level they think they are the exception. Acceptance is knowing you must care for your health because it is the foundation for everything else. Without health, everything else multiplies by zero.

We are tempted to believe we're the exception because it's the easy path.

Aligning with the world often requires you to pre-pay now for a result later. A little bit of pain today for gain tomorrow. And we don't like the sounds of that.

However, if you can align yourself with the world despite what those around you do, you'll quickly discover that it tends to do most of the work for you. It just won't take the first step for you. You have to take that one for yourself.

68. The Central Mistake of Historicism: Karl Popper on Why Trend is Not Destiny

Philosophy can be a little dry in concept. The word itself conjures up images of *thinking about thought, why we exist*, and other metaphysical ideas that seem a little divorced from the everyday world.

One true philosopher who bucked the trend was the genius Austrian philosopher of science, Karl Popper.

Popper had at least three important lines of inquiry:

1. How does progressive scientific thought actually happen?
2. What type of society do we need to allow for scientific progress to be made?
3. What can we say we actually know about the world?

Popper's work led to his idea of falsifiability as the main criterion of a scientific theory. Simply put, an idea or theory doesn't enter the realm of *science* until we can state it in such a way that a test could prove it wrong. This important identifier allowed him to distinguish between science and pseudoscience.

An interesting piece of Popper's work was an attack on what he called *historicism* — the idea that history has fixed laws or trends that inevitably lead to certain outcomes. Included would be the Marxist interpretation of human history as a push and pull between classes, the Platonic ideals of the systemic "rise and fall" of cities and societies in a fundamentally predictable way, John Stuart Mill's *laws of succession*, and even the theory that humanity inevitably progresses towards a "better" and happier outcome, however defined. Modern ideas in this category might well include Thomas Piketty's theory of how capitalism leads to an accumulation of dangerous inequality, the "inevitability" of America's fall from grace in the fashion of the Roman empire, or even Russell Brand's popular diatribe on utopian upheaval from a few years back.

Popper considered this kind of thinking pseudoscience, or worse — a dangerous ideology that tempts wannabe state planners and utopians to control society. (Perhaps through violent revolution, for example.) He did not consider such *historicist* doctrines falsifiable. There is no way, for example, to test whether Marxist theory is actually true or not, even in a thought experiment. We must simply take it on faith, based on a certain interpretation of history, that the bourgeoisie and the proletariat are at odds, and that the latter is destined to create uprisings. (*Destined* being the operative word — it implies inevitability.) If we're to assert that there is a *Law of Increasing Technological Complexity* in human society, which many are tempted to do these days, is that actually a testable hypothesis? Too frequently, these *Laws* become immune to falsifying evidence — any new evidence is interpreted through the lens of the theory. Instead of calling them interpretations, we call them *Laws*, or some similarly connotative word.

More deeply, Popper realized the important point that *history is a unique process* — it only gets run once. We can't derive *Laws of History* that predict the future the way we can with, say, a *law of physics* that carries predictive capability under stated conditions. (i.e. If I drop a ceramic coffee cup more than 2 feet, it will shatter.) We can only merely deduce some tendencies of human nature, laws of the physical world, and so on, and generate some reasonable expectation that if X happens, Y is somewhat likely to follow. But viewing the process of human or organic history as possessing the regularity of a solar system is folly. He discusses this in his book *The Poverty of Historicism*.

The evolution of life on earth, or of a human society, is a unique historical process. Such a process, we may assume, proceeds in accordance with all kinds of causal laws, for example, the laws of mechanics, of chemistry, of heredity and segregation, of natural selection, etc. Its description, however, is not a law, but only a single historical statement. Universal laws make assertions concerning some unvarying order[...] and

although there is no reason why the observation of one single instance should not incite us to formulate a universal law, nor why, if we are lucky, we should not even hit upon the truth, it is clear that any law, formulated in this or in any other way, must be tested by new instances before it can be taken seriously by science. But we cannot hope to test a universal hypothesis nor to find a natural law acceptable to science if we are ever confined to the observation of one unique process. Nor can the observation of one unique process help us to foresee its future development. The most careful observation of one developing caterpillar will to help us to predict its transformation into a butterfly.

Popper realized that once we deduce a theory of the Laws of Human Development, carried into the ever-after, we are led into a gigantic confirmation bias problem. For example, we can certainly find confirmations for the idea that humans have *progressed*, in a specifically defined way, towards increasing technological complexity. But is that a Law of history, in the inviolable sense? For that, we really can't say.

The problem is that to establish cause-and-effect, in a scientific sense, requires two things: A universal law (or a set of them) and some initial conditions (and ideally these are played out over a really large sample size to give us confidence). Popper explains:

*I suggest that to give a causal explanation of a certain specific event means deducing a statement describing this event from two kinds of premises: from some universal laws, and from some singular or specific statements which we may call specific initial conditions. For example, we can say that we have given a causal explanation of the breaking of a certain thread if we find this thread could carry a weight of only one pound, and that a weight of two pounds was put on it. If we analyze this causal explanation, then we find that two different constituents are involved. (1) Some hypotheses of the character of universal laws of nature; in this case, perhaps: 'For every thread of a given structure *s* (determined by material, thickness, etc.) there is a characteristic weight *w* such that the thread will break if any weight exceeding *w* is suspended on it' and 'For every thread of the structure *s*, the characteristic weight *w* equals one pound.' (2) Some specific statements—the initial conditions—pertaining to the particular event in question; in this case we may have two such statements: 'This is a thread of structure *s*, and 'The weight put on this thread was a weight of two pounds'.*

The trend is
not destiny

Here we hit on the problem of trying to assert any fundamental laws by which human history must inevitably progress. Trend is not destiny. Even if we can derive and understand certain laws of human biological nature, the trends of history itself dependent on conditions, and conditions change.

Explained trends do exist, but their persistence depends on the persistence of certain specific initial conditions (which in turn may sometimes be trends).

Mill and his fellow historicists overlook the dependence of trends on initial conditions. They operate with trends as if they were unconditional, like laws. Their confusion of laws with trends make them believe in trends which are unconditional (and therefore general); or, as we may say, in 'absolute trends'; for example a general historical tendency towards progress—'a tendency towards a better and happier state'. And if they at all consider a 'reduction' of their tendencies to laws, they believe that these tendencies can be immediately derived from universal laws alone, such as the laws of psychology (or dialectical materialism, etc.).

This, we may say, is the central mistake of historicism. Its "laws of development" turn out to be absolute trends; trends which, like laws, do not depend on initial conditions, and which carry us irresistibly in a certain direction into the future. They are the basis of unconditional prophecies, as opposed to conditional scientific predictions.

[...]

The point is that these (initial) conditions are so easily overlooked. There is, for example, a trend towards an 'accumulation of means of production' (as Marx puts it). But we should hardly expect it to persist in a population which is rapidly decreasing; and such a decrease may in turn depend on extra-economic conditions, for example, on chance interventions, or conceivably on the direct physiological (perhaps bio-chemical) impact of an industrial environment. There are, indeed, countless possible conditions; and in order to be able to examine these possibilities in our search for the true conditions of the trend, we have all the time to try to imagine conditions under which the trend in question would disappear. But this is just what the historicist cannot do. He firmly believes in his favorite trend, and conditions under which it would disappear to him are unthinkable. The poverty of historicism, we might say, is a poverty of imagination. The historicist continuously upbraids those who cannot imagine a change in their little worlds; yet it seems that the historicist is himself deficient in imagination, for he cannot imagine a change in the conditions of change.

69. The Munger Operating System: How to Live a Life That Really Works

In 2007, Charlie Munger gave the commencement address at USC Law School, opening his speech by saying, *“Well, no doubt many of you are wondering why the speaker is so old. Well, the answer is obvious: He hasn’t died yet.”*

Fortunately for us, Munger has kept on ticking. The commencement speech is an excellent response to the Big Question: *How do we live a life that really works?* It has so many of Munger’s core ideas that we think the speech represents the Munger Operating System for life.

To get what you want, deserve what you want. Trust, success, and admiration are earned. *It's such a simple idea. It's the golden rule so to speak: You want to deliver to the world what you would buy if you were on the other end. There is no ethos, in my opinion, that is better for any lawyer or any other person to have. By and large the people who have this ethos win in life and they don't win just money, not just honors. They win the respect, the deserved trust of the people they deal with, and there is huge pleasure in life to be obtained from getting deserved trust.*

Learn to love and admire the right people, alive or dead.

A second idea that I got very early was that there is no love that's so right as admiration-based love, and that love should include the instructive dead. Somehow, I got that idea and I lived with it all my life; and it's been very, very useful to me.

Acquiring wisdom is a moral duty as well as a practical one.

And there's a corollary to that proposition which is very important. It means that you're hooked for lifetime learning, and without lifetime learning you people are not going to do very well. You are not going to get very far in life based on what you already know. You're going to advance in life by what you're going to learn after you leave here...if civilization can progress only when it invents the method of invention, you can progress only when you learn the method of learning.

Attain fluency on the big multidisciplinary ideas of the world and use them regularly.

What I noted since the really big ideas carry 95% of the freight, it wasn't at all hard for me to pick up all the big ideas from all the big disciplines and make them a standard part of my mental routines. Once you have the ideas, of course, they are no good if you don't practice — if you don't practice you lose it.

So I went through life constantly practicing this model of the multidisciplinary approach. Well, I can't tell you what that's done for me. It's made life more fun, it's made me more constructive, it's made me more helpful to others, it's made me enormously rich, you name it, that attitude really helps.

Now there are dangers there, because it works so well, that if you do it, you will frequently find you are sitting in the presence of some other expert, maybe even an expert that's superior to you, supervising you. And you will know more than he does about his own specialty, a lot more. You will see the correct answer when he's missed it.

[...]

It doesn't help you just to know them enough just so you can give them back on an exam and get an A. You have to learn these things in such a way that they're in a mental latticework in your head and you automatically use them for the rest of your life.

Learn to think through problems backwards as well as forward.

The way complex adaptive systems work and the way mental constructs work, problems frequently get easier and I would even say usually are easier to solve if you turn around in reverse.

In other words if you want to help India, the question you should ask is not "how can I help India?", you think "what's doing the worst damage in India? What would automatically do the worst damage and how do I avoid it?" You'd think they are logically the same thing, but they're not. Those of you who have mastered algebra know that inversion frequently will solve problems which nothing else will solve. And in life, unless you're more gifted than Einstein, inversion will help you solve problems that you can't solve in other ways.

Be reliable. Unreliability can cancel out the other virtues.

If you're unreliable it doesn't matter what your virtues are, you're going to crater immediately. So doing what you have faithfully engaged to do should be an automatic part of your conduct. You want to avoid sloth and unreliability.

Avoid intense ideologies. Always consider the other side as carefully as your own.

Another thing I think should be avoided is extremely intense ideology, because it cabbages up one's mind. You've seen that. You see a lot of it on TV, you know preachers for instance, they've all got different ideas about theology and a lot of them have minds that are made of cabbage.

But that can happen with political ideology. And if you're young it's easy to drift into loyalties and when you announce that you're a loyal member and you start shouting the orthodox ideology out what you're doing is pounding it in, pounding it in, and you're gradually ruining your mind. So you want to be very careful with this ideology. It's a big danger.

In my mind I have a little example I use whenever I think about ideology, and it's these Scandinavian canoeists who succeeded in taming all the rapids of Scandinavia and they thought they would tackle the whirlpools in the Grand Rapids here in the United States. The death rate was 100%. A big whirlpool is not something you want to go into and I think the same is true about a really deep ideology.

I have what I call an iron prescription that helps me keep sane when I naturally drift toward preferring one ideology over another. And that is I say "I'm not entitled to have an opinion on this subject unless I can state the arguments against my position better than the people do who are supporting it. I think that only when I reach that stage am I qualified to speak." Now you can say that's too much of an iron discipline..it's not too much of an iron discipline. It's not even that hard to do.

Get rid of self-serving bias, envy, resentment, and self-pity.

Generally speaking, envy, resentment, revenge and self pity are disastrous modes of thought. Self-pity gets pretty close to paranoia, and paranoia is one of the very hardest things to reverse. You do not want to drift into self-pity.

I have a friend who carried a big stack of index cards about this thick, and when somebody would make a comment that reflected self pity, he would take out one of the cards, take the top one off the stack and hand it to the person, and the card said, "Your story has touched my heart, never have I heard of anyone with as many misfortunes as you". Well, you can say that's waggery, but I suggest that every time you find you're drifting into self pity, I don't care what the cause — your child could be dying of cancer — self-pity is not going to improve the situation. Just give yourself one of those cards.

It's a ridiculous way to behave, and when you avoid it you get a great advantage over everybody else, almost everybody else, because self-pity is a standard condition and yet you can train yourself out of it.

And of course self-serving bias, you want to get that out of yourself; thinking that what's good for you is good for the wider civilization and rationalizing all these ridiculous conclusions based on the subconscious tendency to serve one's self.

At the same time, allow for the self-serving bias in others who haven't removed it.

You also have to allow for the self serving bias of everybody else, because most people are not going to remove it all that successfully, the human condition being what it is. If you don't allow for self serving bias in your conduct, again you're a fool.

I watched the brilliant Harvard Law School trained general counsel of Salomon lose his career, and what he did was when the CEO became aware that some underling had done something wrong, the general counsel said, "Gee, we don't have any legal duty to report this but I think it's what we should do it's our moral duty."

Of course, the general counsel was totally correct but of course it didn't work; it was a very unpleasant thing for the CEO to do and he put it off and put it off and of course everything eroded into a major scandal and down went the CEO and the general counsel with him.

The correct answer in situations like that was given by Ben Franklin, he said, "If you want to persuade, appeal to interest not to reason." The self serving bias is so extreme. If the general counsel had said, "Look this is going to erupt, it's something that will destroy you, take away your money, take away your status...it's a perfect disaster," it would have worked!

Avoid being part of a system with perverse incentives.

Incentives are too powerful a controller of human cognition and human behavior, and one of the things you are going to find in some modern law firms is billable hour quotas. I could not have lived under a billable hour quota of 2,400 hours a year. That would have caused serious problems for me — I wouldn't have done it and I don't have a solution for you for that. You'll have to figure it out for yourself but it's a significant problem.

Work with and under people you admire, and avoid the inverse when at all possible.

And that requires some talent. The way I solved that is, I figured out the people I did admire and I maneuvered cleverly without criticizing anybody, so I was working entirely under people I admired. And a lot of law firms will permit that if you're shrewd enough to work it out. And your outcome in life will be way more satisfactory and way better if you work under people you really admire. The alternative is not a good idea.

Learn to maintain your objectivity, especially when it's hardest.

Well we all remember that Darwin paid special attention to disconfirming evidence particularly when it disconfirmed something he believed and loved. Well, objectivity maintenance routines are totally required in life if you're going to be a correct thinker. And there we're talking about Darwin's attitude, his special attention to disconfirming evidence, and also to checklist routines. Checklist routines avoid a lot of errors. You should have all this elementary wisdom and then you should go through and have a checklist in order to use it. There is no other procedure that will work as well.

Concentrate experience and power into the hands of the right people — the wise learning machines.

I think the game of life in many respects is getting a lot of practice into the hands of the people that have the most aptitude to learn and the most tendency to be learning machines. And if you want the very highest reaches of human civilization that's where you have to go.

You do not want to choose a brain surgeon for your child among fifty applicants all of them just take turns during the procedure. You don't want your airplanes designed that way. You don't want your Berkshire Hathaways run that way. You want to get the power into the right people.

You'll be most successful where you're most intensely interested.

Another thing that I found is an intense interest of the subject is indispensable if you are really going to excel. I could force myself to be fairly good in a lot of things, but I couldn't be really good in anything where I didn't have an intense interest. So to some extent, you're going to have to follow me. If at all feasible you want to drift into doing something in which you really have a natural interest.

Learn the all-important concept of assiduity: Sit down and do it until it's done.

Two partners that I chose for one little phase of my life had the following rule: They created a little design/build construction team, and they sat down and said, two-man partnership, divide everything equally, here's the rule; "Whenever we're behind in our commitments to other people, we will both work 14 hours a day until we're caught up."

Well, needless to say, that firm didn't fail. The people died rich. It's such a simple idea.

Use setbacks in life as an opportunity to become a bigger and better person. Don't wallow.

Another thing of course is life will have terrible blows, horrible blows, unfair blows, doesn't matter. And some people recover and others don't. And there I think the attitude of Epictetus is the best. He thought that every mischance in life was an opportunity to behave well, every mischance in life was an opportunity to learn something, and your duty was not to be submerged in self-pity but to utilize the terrible blow in a constructive fashion. That is a very good idea.

The highest reach of civilization is a seamless system of trust among all parties concerned.

The last idea that I want to give you as you go out into a profession that frequently puts a lot of procedure and a lot of precautions and a lot of mumbo jumbo into what it does, this is not the highest form which civilization can reach. The highest form which civilization can reach is a seamless web of deserved trust. Not much procedure, just totally reliable people correctly trusting one another. That's the way an operating room works at the Mayo Clinic. If a bunch of lawyers were to introduce a lot of process, the patients would all die. So never forget when you're a lawyer that you may be rewarded for selling this stuff but you don't have to buy it. In your own life what you want is a seamless web of deserved trust. And if your proposed marriage contract has 47 pages, my suggestion is do not enter.

70. 12 Things Lee Kuan Yew Taught Me About the World

"It's no accident that Singapore has a much better record, given where it started, than the United States. There, power was concentrated in one enormously talented person, Lee Kuan Yew, who was the Warren Buffett of Singapore."

— Charlie Munger

Singapore seemed destined for failure or subservience to a more powerful neighbor. The country is by far the smallest in Southeast Asia and was not gifted with many natural resources. Lee Kuan Yew thought otherwise. "His vision," wrote Henry Kissinger, "was of a state that would not simply survive, but prevail by excelling. Superior intelligence, discipline, and ingenuity would substitute for resources."

To give you an idea of the magnitude of success that Lee Kuan Yew achieved, when he took over, per capita income was about \$400 and now, in only about two generations, it exceeds \$50,000.

Here are 12 things I learned from Lee Kuan Yew about the world and the source of many of our present ills reading *Lee Kuan Yew: The Grand Master's Insights on China, the United States, and the World*.

1. You need a free exchange of ideas. "China will inevitably catch up to the U.S. in absolute GDP. But its creativity may never match America's, because its culture does not permit a free exchange and contest of ideas."
2. Technology will change how governance operates. "Technology is going to make (China's) system of governance obsolete. By 2030, 70% or maybe 75% of their people will be in cities, small towns, big towns, mega big towns. They are going to have cell phones, Internet, satellite TV. They are going to be well-informed; they can organize themselves. You cannot govern them the way you are governing them now, where you just placate and monitor a few people, because the numbers will be so large."
3. Don't try to install a democracy in a country that has never had one. "I do not believe you can impose on other countries standards which are alien and totally disconnected with their past. So to ask China to become a democracy, when in its 5,000 years of recorded history it never counted heads; all rulers ruled by right of being the emperor, and if you disagree, you chop off heads, not count heads."
4. Welcome the best the world has to offer. "Throughout history, all empires that succeeded have embraced and included in their midst people of other races, languages, religions, and cultures."
5. It's about results, not promises. "When you have a popular democracy, to win voices you have to give more and more. And to beat your opponent in the next election, you have to promise to give more away. So it is a never-ending process of auctions—and the cost, the debt being paid for by the next generation. Presidents do not get reelected if they give a hard dose of medicine to their people. So, there is a tendency to procrastinate, to postpone unpopular policies in order to win elections. So problems such as budget deficits, debt, and high unemployment have been carried forward from one administration to the next."
6. Governments shouldn't have an easy way out. "American and European governments believed that they could always afford to support the poor and the needy: widows, orphans, the old and homeless, disadvantaged minorities, unwed mothers. Their sociologists expounded the theory that hardship and failure were due not to the individual person's character, but to flaws in the economic system. So

charity became “entitlement,” and the stigma of living on charity disappeared. Unfortunately, welfare costs grew faster than the government’s ability to raise taxes to pay for it. The political cost of tax increases is high. Governments took the easy way out by borrowing to give higher benefits to the current generation of voters and passing the costs on to the future generations who were not yet voters. This resulted in persistent government budget deficits and high public debt.”

7. What goes into a standard of living? “A people’s standard of living depends on a number of basic factors: first, the resources it has in relation to its population . . . ; second, its level of technological competence and standards of industrial development; third, its educational and training standards; and fourth, the culture, the discipline and drive in the workforce.”
8. The single most important factor to national competitiveness ... “The quality of a nation’s manpower resources is the single most important factor determining national competitiveness. It is a people’s innovativeness, entrepreneurship, team work, and their work ethic that give them the sharp keen edge in competitiveness. Three attributes are vital in this competition—entrepreneurship to seek out new opportunities and to take calculated risks. Standing still is a sure way to extinction. . . . The second attribute, innovation, is what creates new products and processes that add value. . . . The third factor is good management. To grow, company managements have to open up new markets and create new distribution channels. The economy is driven by the new knowledge, new discoveries in science and technology, innovations that are taken to the market by entrepreneurs. So while the scholar is still the greatest factor in economic progress, he will be so only if he uses his brains—not in studying the great books, classical texts, and poetry, but in capturing and discovering new knowledge, applying himself in research and development, management and marketing, banking and finance, and the myriad of new subjects that need to be mastered.”
9. Earning your place in history ... “A nation is great not by its size alone. It is the will, the cohesion, the stamina, the discipline of its people, and the quality of their leaders which ensure it an honorable place in history.”
10. Weak leaders rely on opinion polls. “I have never been overconcerned or obsessed with opinion polls or popularity polls. I think a leader who is, is a weak leader. If you are concerned with whether your rating will go up or down, then you are not a leader. You are just catching the wind ... you will go where the wind is blowing. . . . Between being loved and feared, I have always believed Machiavelli was right. If nobody is afraid of me, I am meaningless. When I say something ... I have to be taken very seriously.”
11. We are fundamentally competitive. “Human beings are not born equal. They are highly competitive. Systems like Soviet and Chinese communism have failed, because they tried to equalize benefits. Then nobody works hard enough, but everyone wants to get as much as, if not more than, the other person.”
12. The value of history: “If you do not know history, you think short term. If you know history, you think medium and long term.”

71. The Four Tools of Discipline

"The life of wisdom must be a life of contemplation combined with action."

Life is full of problems. We can moan about them, or we can solve them. Scott Peck argues in The Road Less Traveled: A New Psychology of Love, Traditional Values and Spiritual Growth that discipline is the toolbox for solving problems.

Peck's argument is based on the notion that most of us want to avoid problems – they are painful and often lead us to confront our humanity. They are frustrating. There are false starts. We lack consistent frameworks for improvement. They cause us to feel sad and lonely; things we'd rather avoid. The mental pain and strain often rival physical pain. Yet Peck argues it is in this "whole process of meeting and solving problems that life has meaning."

Problems call forth our courage and our wisdom; indeed, they create our courage and our wisdom. It is only because of problems that we grow mentally and spiritually. When we desire to encourage the growth of the human spirit, we challenge and encourage the human capacity to solve problems, just as in school we deliberately set problems for our children to solve. It is through the pain of confronting and resolving problems that we learn. As Benjamin Franklin said, "Those things that hurt, instruct."

This is why some of us come to welcome problems. Most of us, however, fear them. *Fearing the pain involved, almost all of us, to a greater or lesser degree, attempt to avoid problems. We procrastinate, hoping that they will go away. We ignore them, forget them, pretend they do not exist. We even take drugs to assist us in ignoring them, so that by deadening ourselves to the pain we can forget the problems that cause the pain. We attempt to skirt around problems rather than meet them head on. We attempt to get out of them rather than suffer through them.*

Ultimately however, the suffering from avoiding reality is more painful than reality itself. You can see where this goes right? Now we want to avoid the pseudo-reality that we created to avoid reality. And so it builds, layer on layer.

Avoiding problems avoids the opportunity for growth. Most of the time, problems don't go away, instead they grow.

This inclination to ignore problems is once again a simple manifestation of an unwillingness to delay gratification. Confronting problems is, as I have said, painful. To willingly confront a problem early, before we are forced to confront it by circumstances, means to put aside something pleasant or less painful for something more painful. It is choosing to suffer now in the hope of future gratification rather than choosing to continue present gratification in the hope that future suffering will not be necessary.

The Four Tools of Discipline

There are four tools of discipline: delaying of gratification, acceptance of responsibility, dedication to truth, and balancing

These are easy to learn and yet hard to employ.

1. Delaying Gratification

Delaying gratification is a process of scheduling the pain and pleasure of life in such a way as to enhance the pleasure by meeting and experiencing the pain first and getting it over with. It is the only decent way to live.

2. Accepting Responsibility

The extent to which we will go to avoid responsibility should come as no surprise.

Accepting responsibility is emotionally uncomfortable.

We often feel, incorrectly, that we can solve a problem by saying, "That's not my problem."

Other times we hope that someone else will just solve it for us.

I can solve a problem only when I say "This is my problem and it's up to me to solve it."

But many, so many, seek to avoid the pain of their problems by saying to themselves: "This problem was caused me by other people, or by social circumstances beyond my control,

and therefore it is up to other people or society to solve this problem for me. It is not really my personal problem."

There are extremes of responsibility.

The neurotic assumes too much responsibility; the person with a character disorder not enough. When neurotics are in conflict with the world they automatically assume that they are at fault. When those with character disorders are in conflict with the world they automatically assume that the world is at fault.

Just remember ...

Whenever we seek to avoid the responsibility for our own behavior, we do so by attempting to give that responsibility to some other individual, organization, or entity.

3. Dedication to Reality

This sounds a lot like Joseph Tussman's wise advice. Most of us have problems confronting reality because it does not line up with how we want the world to work. The rise of a political figure that we don't support baffles us because in our mind the world shouldn't work that way.

What Peck outlines below is a version of the map and territory problem.

Superficially, this should be obvious. For truth is reality. That which is false is unreal. The more clearly we see the reality of the world, the better equipped we are to deal with the world. The less clearly we see the reality of the world—the more our minds are befuddled by falsehood, misperceptions and illusions—the less able we will be to determine correct courses of action and make wise decisions. Our view of reality is like a map with which to negotiate the terrain of life. If the map is true and accurate, we will generally know where we are, and if we have decided where we want to go, we will generally know how to get there. If the map is false and inaccurate, we generally will be lost.

While this is obvious, it is something that most people to a greater or lesser degree choose to ignore. They ignore it because our route to reality is not easy. First of all, we are not born with maps; we have to make them, and the making requires effort. The more effort we make to appreciate and perceive reality, the larger and more accurate our maps will be. But many do not want to make this effort. Some stop making it by the end of adolescence. Their maps are small and sketchy, their views of the world narrow and misleading. By the end of middle age most people have given up the effort. They feel certain that their maps are complete and their Weltanschauung is correct (indeed, even sacrosanct), and they are no longer interested in new information. ... Only a relative and fortunate few continue until the moment of death exploring the mystery of reality, ever enlarging and refining and redefining their understanding of the world and what is true.

This biggest problem isn't that our maps are inaccurate but rather that we fail, especially as we age, to revise them. The world is always changing. As Heraclitus said, No man can step in the same river twice.

The world itself is constantly changing. Glaciers come, glaciers go. Cultures come, cultures go. There is too little technology, there is too much technology. Even more dramatically, the vantage point from which we view the world is constantly and quite rapidly changing.

When we've worked so hard over so many years to create a map that we believe represents the world, we tend to ignore information that would suggest we need to redraw our map. We become defensive. Often we don't even passively ignore this information. We go further. We denounce it or crusade against it. We feel that people who listen to it are idiots, and we are the only ones who see the truth. Rather than change our map, we often try to (mentally) destroy the new reality and those that subscribe to it.

Pride and ego come into play.

Truth or reality is avoided when it is painful. We can revise our maps only when we have the discipline to overcome that pain. To have such discipline, we must be totally dedicated to truth. That is to say that we must always hold truth, as best we can determine it, to be

more important, more vital to our self-interest, than our comfort. Conversely, we must always consider our personal discomfort relatively unimportant and, indeed, even welcome it in the service of the search for truth.

Openness to Challenge

What does a life of total dedication to the truth mean? It means, first of all, a life of continuous and never-ending stringent self-examination. We know the world only through our relationship to it. Therefore, to know the world, we must not only examine it but we must simultaneously examine the examiner.

The only way we can ensure our map is correct and accurate is to expose it to the criticism of others. There might be a better answer than the one you have. We need an outside view. Otherwise, we live in a closed system. The tendency to avoid being challenged is a characteristic of human nature.

4. Balancing

Balancing is the discipline that gives us flexibility. Extraordinary flexibility is required for successful living in all spheres of activity.

[...]

To function successfully in our complex world it is necessary for us to possess the capacity not only to express our anger but also not to express it. Moreover, we must possess the capacity to express our anger in different ways. At times, for instance, it is necessary to express it only after much deliberation and self-evaluation. At other times it is more to our benefit to express it immediately and spontaneously. Sometimes it is best to express it coldly and calmly; at other times loudly and hotly. We therefore not only need to know how to deal with our anger in different ways at different times but also how most appropriately to match the right time with the right style of expression. To handle our anger with full adequacy and competence, an elaborate, flexible response system is required. It is no wonder, then, that to learn to handle our anger is a complex task which usually cannot be completed before adulthood, or even mid-life, and which often is never completed.

[...]

Balancing is a discipline precisely because the act of giving something up is painful.

72. Don't Let Your (Technology) Tools Use You

"In an information-rich world, the wealth of information means a dearth of something else: a scarcity of whatever it is that information consumes.

What information consumes is rather obvious: it consumes the attention of its recipients. Hence a wealth of information creates a poverty of attention and a need to allocate that attention efficiently among the overabundance of information sources that might consume it."

— Herbert Simon

A shovel is just a shovel. You shovel things with it. You can break up weeds and dirt. (You can also whack someone with it.) I'm not sure I've seen a shovel used for much else.

Modern technological tools aren't really like that.

What is an iPhone, functionally? Sure, it's got the *phone* thing down, but it's also a GPS, a note-taker, an emailer, a text messenger, a newspaper, a video-game device, a taxi-calling service, a flashlight, a web browser, a library, a book...you get the point. It does a lot.

This all seems pretty wonderful. To perform those functions 20 years ago, you needed a map and a sense of direction, a notepad, a personal computer, a cell phone, an actual newspaper, a Playstation, a phone and the willingness to talk to a person, an actual flashlight, an actual library, an actual book...you get the point. As Mark Andreessen puts it, the world is being eaten by software. One simple (looking) device and a host of software can perform the functions served by a bunch of big clunky tools of the past.

So far, we've been convinced that use of the New Tools is mostly "upside," that our embrace of them should be wholehearted. Much of this is for good reason. Do you remember how awful using a map was? Yuck.

The problem is that our New Tools are winning the battle of attention. We've gotten to the point where the tools use us as much as we use them. This new reality means we need to re-examine our relationship with our New Tools.

Down the Rabbit Hole

Here's a typical situation.

You're on your computer finishing the client presentation you have to give in two days.

Your phone lights up and makes a chimney noise — you've got a text message. "Hey, have you seen that new Dracula movie?" asks your friend. It only takes a few messages

before the two of you begin to disagree on whether Transylvania is actually a real place. Off to Google!

After a few quick clicks, you get to Wikipedia, which tells you that yes, Transylvania is a region of Romania which the author Bram Stoker used as Count Dracula's birthplace. Reading the Wikipedia entry costs you about 20 minutes. As you read, you find out that Bram Stoker was actually Irish. Irish! An Irish guy wrote Dracula? How did I not know this? Curiosity stoked, you look up Irish novelists, the history of Gothic literature, the original vampire stories...down and down the rabbit hole you go.

Eventually your thirst for trivia is exhausted, and you close the Wikipedia tab to text your friend how wrong they are in regards to Transylvania. You click the Home button to leave your text conversation, which lets you see the Twitter icon. I wonder how many people retweeted my awesome joke about ventriloquism? You pull it up and start "The Scroll." Hah! Greg is hilarious. Are you serious, Bill Gates? Damn — I wish I read as much as Shane Parrish. You go and go. Your buddy tweets a link to an interesting-looking article about millennials — "10 Ways Millennials are Ruining the Workplace". God, they are so self-absorbed. Click.

You decide to check Facebook and see if that girl from the cocktail party on Friday commented on your status. She didn't, but Wow, Susanne went to Hawaii? You look at 35 pictures Susanne posted in her first three hours in Hawaii. Wait, who's that guy she's with? You click his name and go to his Facebook page. On down the rabbit hole you fall...

Now it's been two hours since you left your presentation to respond to the text message, and you find yourself physically tired from the rapid scanning and clicking, scanning and clicking, scanning and clicking of the past two hours. Sad, you go get a coffee, go for a short walk, and decide: Now, I will focus. No more distraction.

Ten minutes in, your phone buzzes. That girl from the cocktail party commented on your status...

Attention for Sale

We've all been there. When we come up for air, it can feel like the aftermath of a mob crowd. *What did I just do?*

The tools we're now addicted to have been engineered for a simple purpose: To keep us addicted to them. The service they provide is secondary to the addiction. Yes, Facebook is a networking tool. Yes, Twitter is a communication tool. Yes, Instagram is an excellent food-photography tool. But unless they get us hooked and keep us hooked, their business models are broken.

Don't believe us?

Take stock of the metrics by which people value or assess these companies. Clicks. Views. Engagement. Return visits. Length of stay. The primary source of value for these products is how much you use them and what they can sell to you while you're there. Increasing their value is a simple (but not easy) proposition: Either get usage up or figure out more effective ways to sell to you while you're there.

As Herbert Simon might have predicted, our attention is for sale, and we're ceding it a little at a time as the tools get better and better at fulfilling their function. There's a version of natural selection going on, where the only consumer technology products that survive are the enormously addictive ones. The trait which produces maximum fitness is addictiveness itself. If you're not using a tool constantly, it has no value to advertisers or data sellers, and thus they cannot raise capital to survive. And even if it's an app or tool that you buy, one that you have to pay money for upfront, they must hook you on Version 1 if you're going to be expected to buy Versions 2, 3, and 4.

This ecosystem ensures that each generation of consumer tech products — hardware or software — gets better and better at keeping you hooked. These services have learned, through a process of evolution, to drown users in positive feedback and create intense habitual usage. They must — because any other outcome is death. Facebook doesn't want

you to go on once a month to catch up on your correspondence. You must be engaged. The service does not care whether it's unnecessarily eating into your life.

Snap Back to Reality

It's up to us to take our lives back then. We must comprehend that the New Tools have a tremendous downside in their loss of focused attention, and that we're giving it up willingly in a sort of Faustian bargain for entertainment, connectedness, and novelty.

Psychologist Mihaly Csikszentmihalyi pioneered the concept of Flow, where we enter an enjoyable state of rapt attention to our work and produce a high level of creative output. It's a wonderful feeling, but the New Tools have learned to provide the same sensation without the actual results. We don't end up with a book, or a presentation, or a speech, or a quilt, or a hand-crafted table. We end up two hours later in the day.

The first step towards a solution must be to understand the reality of this new ecosystem. It follows Garrett Hardin's "First Law of Ecology": You can never merely do one thing. The New Tools are not like the Old Tools, where you pick up the shovel, do your shoveling, and then put the shovel back in the garage. The iPhone is not designed that way. It's designed to keep you going, as are most of the other New Tools. You probably won't send one text. You probably won't watch one video. You probably won't read one article. You're not supposed to!

The rational response to this new reality depends a lot on who you are and what you need the tools for. Some people can get rid of 50% or more of their New Tools very easily. You don't have to toss out your iPhone for a StarTAC, but because software is doing the real work, you can purposefully reduce the capability of the hardware by reducing your exposure to certain software.

As you shed certain tools, expect a homeostatic response from your network. Don't be mistaken: If you're a Snapper or an Instagrammer or simply an avid texter, getting rid of those services will give rise to consternation. They are, after all, networking tools. Your network will notice. You'll need a bit of courage to face your friends and tell them, with a straight face, that you won't be Instagramming anymore because you're afraid of falling down the rabbit hole. But if you've got the courage, you'll probably find that after a week or two of adjustment your life will go on just fine.

The second and more mild type of response would be to appreciate the chain-smoking nature of these products and to use them more judiciously. Understand that every time you look at your iPhone or connect to the Internet, the rabbit hole is there waiting for you to tumble down. If you can grasp that, you'll realize that you need to be suspicious of the "quick check." Either learn to batch Internet and phone time into concentrated blocks or slowly re-learn how to ignore the desire to follow up on every little impulse that comes to mind. (Or preferably, do both.)

A big part of this is turning off any sort of "push" notification, which must be the most effective attention-diverter ever invented by humanity. A push notification is anything that draws your attention to the tool without your conscious input. It's when your phone buzzes for a text message, or an image comes on the screen when you get an email, or your phone tells you that you've got a Facebook comment. Anything that desperately induces you to engage. You need to turn them off. (Yes, including text message notifications – your friends will get used to waiting).

E-mail can be the worst offender; it's the earliest and still one of the most effective digital rabbit holes. To push back, close your email client when you're not using it. That way, you'll have to open it to send or read an email. Then go ahead and change the settings on your phone's email client so you have to "fetch" emails yourself, rather than having them pushed at you. Turn off anything that tells you an email has arrived.

Once you stop being notified by your tools, you can start to engage with them on your own terms and focus on your real work for a change; focus on the stuff actually producing some

value in your life and in the world. When the big stuff is done, you can give yourself a half-hour or an hour to check your Facebook page, check your Instagram page, follow up on Wikipedia, check your emails, and respond to your text messages. This isn't as good a solution as deleting many of the apps altogether, but it does allow you to engage with these tools on your own terms.

However you choose to address the world of New Tools, you're way ahead if you simply recognize their power over your attention. Getting lost in hyperlinks and Facebook feeds doesn't mean you're weak, it just means the tools you're using are designed, at their core, to help you get lost. Instead of allowing yourself to go to work for them, resolve to make them work for you.

73. Mental Models: Getting the World to Do the Work for You

People are working harder and harder to clean up otherwise avoidable messes they created by making poor initial decisions. There are many reasons we're making poor decisions and failing to learn from them.

Under the heading, Sources of Stupidity in an article entitled Smart Decisions we wrote about some of the factors that contribute to suboptimal decisions.

1. We're (sometimes) stupid. Of course, I like to think that I'm rational and capable of interpreting all of the information in a non-biased way. Only I'm not. At least not always. There are situations that increase the odds of irrationality, for instance when we're tired, overly focused on a goal, rushing, distracted or interrupted, operating in a group, or are under the direction of an expert.

2. We have the wrong information. In this case, we're operating with the wrong facts or our assumptions are incorrect.

3. We use the wrong model. We use models to make decisions. The quality of those models often determines the quality of our thinking. There are a variety of reasons that we use false, incomplete, or incorrect models. For instance, we're prone to using less useful models when we are a novice or we operate in a domain outside of our area of expertise. The odds of the wrong model also increase as the pace of environmental change increases.

4. We fail to learn. We all know the person that has 20 years of experience but it's really the same year over and over. Well, that person is sometimes us. If we don't understand how we learn, we're likely to make the same mistakes over and over.

5. Doing what's easy over what's right. You can think of this as looking good over doing good. In this case, we make choices based on optics, explainability, politics, etc. Mostly this comes from not having a strong sense of self and seeking external validation or avoiding punishment.

Simple But Not Easy

One of the metamodels that traverse all five of these sources of stupidity is understanding the world.

If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.

Understanding The World

How can we best understand the world as it is?

Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer.

If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.

This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models.

Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of

bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise?

Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right?

We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

2nd Order Thinking

One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question:

"And then what?"

A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it.

We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal.

For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place.

Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold.

Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins.

We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality.

Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain.

But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise.

Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

74. Alexander von Humboldt and the Invention of Nature: Creating a Holistic View of the World Through A Web of Interdisciplinary Knowledge

In his piece in 2014's Edge collection *This Idea Must Die: Scientific Theories That Are Blocking Progress*, dinosaur paleontologist Scott Sampson writes that science needs to "subjectify" nature. By "subjectify", he essentially means to see ourselves connected with nature, and therefore care about it the same way we do the *people* with whom we are connected.

That's not the current approach. He argues: "One of the most prevalent ideas in science is that nature consists of objects. Of course, the very practice of science is grounded in objectivity. We objectify nature so that we can measure it, test it, and study it, with the ultimate goal of unraveling its secrets. Doing so typically requires reducing natural phenomena to their component parts."

But this approach is ultimately failing us.

Why? Because much of our unsustainable behavior can be traced to a broken relationship with nature, a perspective that treats the nonhuman world as a realm of mindless, unfeeling objects. Sustainability will almost certainly depend upon developing mutually enhancing relations between humans and nonhuman nature.

This isn't a new plea, though. Over 200 years ago, the famous naturalist Alexander Von Humboldt (1769-1859) was facing the same challenges.

In her compelling book *The Invention of Nature: Alexander Von Humboldt's New World*, Andrea Wulf explores Humboldt as the first person to publish works promoting a holistic view of nature, arguing that nature could only be understood in relation to the subjectivity of experiencing it.

Fascinated by scientific instruments, measurements and observations, he was driven by a sense of wonder as well. Of course nature had to be measured and analyzed, but he also believed that a great part of our response to the natural world should be based on the senses and emotions.

Humboldt was a rock star scientist who ignored conventional boundaries in his exploration of nature. Humboldt's desire to know and understand the world led him to investigate discoveries in all scientific disciplines, and to see the interwoven patterns embedded in this knowledge — mental models anyone?

If nature was a web of life, he couldn't look at it just as a botanist, a geologist or a zoologist. He required information about everything from everywhere.

Humboldt grew up in a world where science was dry, nature mechanical, and man an aloof and separate chronicler of what was before him. Not only did Humboldt have a new vision of what our understanding of nature could be, but he put humans in the middle of it.

Humboldt's Essay on the Geography of Plants promoted an entirely different understanding of nature. Instead of only looking at an organism, ... Humboldt now presented relationships between plants, climate and geography. Plants were grouped into zones and regions rather than taxonomic units. ... He gave western science a new lens through which to view the natural world.

Revolutionary for his time, Humboldt rejected the Cartesian ideas of animals as mechanical objects. He also argued passionately against the growing approach in the sciences that put man atop and separate from the rest of the natural world. Promoting a concept of unity in nature, Humboldt saw nature as a "reflection of the whole ... an organism in which the parts only worked in relation to each other."

Furthermore, that "poetry was necessary to comprehend the mysteries of the natural world."

Wulf paints one of Humboldt's greatest achievements as his ability and desire to make science available to everyone. No one before him had "combined exact observation with a 'painterly description of the landscape'".

By contrast, Humboldt took his readers into the crowded streets of Caracas, across the dusty plains of the Llanos and deep into the rainforest along the Orinoco. As he described a continent that few British had ever seen, Humboldt captured their imagination. His words were so evocative, the Edinburgh Review wrote, that 'you partake in his dangers; you share his fears, his success and his disappointment.'

In a time when travel was precarious, expensive and unavailable to most people, Humboldt brought his experiences to anyone who could read or listen.

On 3 November 1827, ... Humboldt began a series of sixty-one lectures at the university. These proved so popular that he added another sixteen at Berlin's music hall from 6 December. For six months he delivered lectures several days a week. Hundreds of people attended each talk, which Humboldt presented without reading from his notes. It was lively, exhilarating and utterly new. By not charging any entry fee, Humboldt democratized science: his packed audiences ranged from the royal family to coachmen, from students to servants, from scholars to bricklayers – and half of those attending were women. Berlin had never seen anything like it.

The subjectification of nature is about seeing nature, experiencing it. Humboldt was a master of bringing people to worlds they couldn't visit, allowing them to feel a part of it. In doing so, he wanted to force humanity to see itself in nature. If we were all part of the giant web, then we all had a responsibility to understand it.

When he listed the three ways in which the human species was affecting the climate, he named deforestation, ruthless irrigation and, perhaps most prophetically, the 'great masses of steam and gas' produced in the industrial centres. No one but Humboldt had looked at the relationship between humankind and nature like this before.

His final opus, a series of books called Cosmos, was the culmination of everything that Humboldt had learned and discovered.

Cosmos was unlike any previous book about nature. Humboldt took his readers on a journey from outer space to earth, and then from the surface of the planet into its inner core. He discussed comets, the Milky Way and the solar system as well as terrestrial magnetism, volcanoes and the snow line of mountains. He wrote about the migration of the human species, about plants and animals and the microscopic organisms that live in stagnant water or on the weathered surface of rocks. Where others insisted that nature was stripped of its magic as humankind penetrated into its deepest secrets, Humboldt believed exactly the opposite. How could this be, Humboldt asked, in a world in which the coloured rays of an aurora 'unite in a quivering sea flame', creating a sight so otherworldly 'the splendour of which no description can reach'? Knowledge, he said, could never 'kill the creative force of imagination' – instead it brought excitement, astonishment and wondrousness.

This is the ultimate subjectivity of nature. Being inspired by its beauty to try and understand how it works. Humboldt had respect for nature, for the wonders it contained, but also as the system in which we ourselves are an inseparable part.

Wulf concludes at the end that Humboldt,

...was one of the last polymaths, and died at a time when scientific disciplines were hardening into tightly fenced and more specialized fields. Consequently his more holistic approach – a scientific method that included art, history, poetry and politics alongside hard data – has fallen out of favour.

Maybe this is where the subjectivity of nature has gone. But we can learn from Humboldt the value of bringing it back.

In a world where we tend to draw a sharp line between the sciences and the arts, between the subjective and the objective, Humboldt's insight that we can only truly understand nature by using our imagination makes him a visionary.

75. How the Many Sides to Every Story Shape our Reality

"We can select truths that engage people and inspire action, or we can deploy truths that deliberately mislead. Truth comes in many forms, and experienced communicators can exploit its variability to shape our impression of reality."

The truth is not as straightforward as it seems. There are many truths, some of them more honest than others. "On most issues," writes Hector Macdonald in his book *Truth: How the Many Sides to Every Story Shape Our Reality*, "there are multiple truths we can choose to communicate. Our choice of truth will influence how those around us perceive an issue and react to it."

We are often left with several truths, some more flattering to us than others. What we choose to see, and what we share with others, says a lot about who we are.

"There is no worse lie than a truth misunderstood by those who hear it."

— William James

Competing Truths

According to MacDonald, there are often many legitimate ways of describing a situation. Of course, it's possible for anyone to cherry-pick the facts or truths they prefer, shaping the story to meet their needs. MacDonald offers an apt demonstration.

A few years ago, I was asked to support a transformation programme at a global corporation that was going through a particularly tough patch. ... I interviewed the corporation's top executives to gather their views on the state of their industry and their organization. After consolidating all the facts they'd given me, I sat down with the CEO in a plush Manhattan executive suite and asked him whether he wanted me to write the 'Golden Opportunity' story or the 'Burning Platform' story of his business.

These two phrases, "Golden Opportunity" and "Burning Platform," describe two different approaches to telling the same story, or in this case, promoting the same plan. The first describes the incredible potential the client company can realize by transforming itself to meet growing demand. The profit is out there for them if they work together to make the necessary changes! The second phrase refers to internal struggles at the company and a potential downward spiral that can only be arrested if the company transforms itself to correct the problems. Both stories are true, and both are intended to create the same outcome: supporting a painful and difficult transformation. Yet they can create very different impressions in the minds of employees.

MacDonald illustrates how, when we interact with someone, especially someone who knows more than we do, they have an opportunity to shape our reality. That is, they can shape how we think, our ideas and opinions about a subject. Our perception of reality changes and "because we act on the basis of our perceptions" they change not only our thinking but our actions.

Spin Masters

I remember watching ads on TV when I was a kid claiming that 80 percent of dentists recommended Colgate-Palmolive. I wondered if my mom was trying to kill me by giving me Crest. I wasn't the best in math, but I reasoned that if 80% of dentists were recommending Colgate, at most 20% were recommending Crest.

Of course, that's exactly what Colgate wanted people to think—the survey was in comparison to other brands. But that wasn't the whole story. The survey actually asked dentists which brands they would recommend, and almost all of them listed several.

Colgate wasn't lying—but they were using a very distorted version of the truth, designed to mislead. The Advertising Standards Authority eventually banned the ad.

People use this sort of spin all the time. Everyone has an agenda. You can deceive without ever lying. Politicians get elected on how effective they are at “spinning truths in a way that create a false impression.” It’s only too easy for political agendas to trump impartial truth.

The Three Types of Communicators

“It’s not simply that we’re being lied to; the more insidious problem is that we are routinely misled by the truth.”

In *Truth*, Macdonald explores the effects of three types of communicators: advocates, misinformers, and misleaders.

Advocates select competing truths that create a reasonably accurate impression of reality in order to achieve a constructive goal.

Misinformers innocently propagate competing truths that unintentionally distort reality.

Misleaders deliberately deploy competing truths to create an impression of reality that they know is not true.

We may feel better believing there is one single truth, and thinking everyone who doesn’t see things the way we do simply doesn’t have the truth. That’s not...true. Everyone, including you and me, has a lens on the situation that’s distorted by what they want, how they see the world, and their biases. The most dangerous truths are the credible ones that we convince ourselves are correct.

One idea I find helpful when faced with a situation is perspective-taking. I construct a mental room that I fill with all the participants and stakeholders around a table. I then put myself into their seats and try to see the room through their eyes. Not only does this help me better understand reality by showing me my blind spots, but it shows me what other people care about and how I can create win-wins.

Truth: How the Many Sides to Every Story Shape Our Reality, goes on to explore partial truths, subjective truths, artificial truths, and unknown truths. It’s a terrific read for checking your own perspective on truth, and understanding how truth can be used to both inform and mislead you.

76. Yuval Noah Harari: Why We Dominate the Earth

Why did Homo sapiens diverge from the rest of the animal kingdom and go on to dominate the earth? Communication? Cooperation? According to best-selling author Yuval Noah Harari, that barely scratches the surface.

Yuval Noah Harari's Sapiens is one of those uniquely breathtaking books that comes along but rarely. It's broad, but scientific. It's written for a popular audience, but never feels dumbed down. It's new and fresh, but not based on any new primary research. *Sapiens* is pure synthesis.

Readers will easily recognize the influence of Jared Diamond, author of Guns, Germs, and Steel, The Third Chimpanzee, and other similarly broad-yet-scientific works with vast synthesis and explanatory power. It's not surprising, then, that Harari, a history professor at the Hebrew University of Jerusalem, has noted Diamond's contributions to his thinking. Harari says:

It [Guns, Germs, and Steel] made me realize that you can ask the biggest questions about history and try to give them scientific answers. But in order to do so, you have to give up the most cherished tools of historians. I was taught that if you're going to study something, you must understand it deeply and be familiar with primary sources. But if you write a history of the whole world you can't do this. That's the trade-off.

Harari sought to understand the history of humankind's domination of the earth and its development of complex modern societies. He applies ideas from evolutionary theory, forensic anthropology, genetics, and the basic tools of the historian to generate a new conception of our past: humankind's success was due to our ability to create and sustain grand, collaborative myths.

To make the narrative more palatable and sensible, we must take a different perspective. Calling us humans keeps us too close to the story to have an accurate view. We're not as unique as we would like to believe. In fact, we're just another animal. We are *Homo sapiens*. Because of this, our history can be described just like that of any other species. Harari labels us like any other species, calling us "Sapiens" so we can depersonalize things and allow the author the room he needs to make some bold statements about the history of humanity. Our successes, failures, flaws and credits are part of the makeup of the Sapiens.[1]

Sapiens existed long before there was recorded history. Biological history is a much longer stretch, beginning millions of years before the evolution of any forbears we can identify. When our earliest known ancestors formed, they were not at the top of the food chain. Rather, they were engaged in an epic battle of trench warfare with the other organisms that shared their habitat.[2]

"Ants and bees can also work together in huge numbers, but they do so in a very rigid manner and only with close relatives. Wolves and chimpanzees cooperate far more flexibly than ants, but they can do so only with small numbers of other individuals that they know intimately. Sapiens can cooperate in extremely flexible ways with countless numbers of strangers. That's why Sapiens rule the world, whereas ants eat our leftovers and chimps are locked up in zoos and research laboratories."

— Yuval Noah Harari, *Sapiens*

These archaic humans loved, played, formed close friendships and competed for status and power, but so did chimpanzees, baboons, and elephants. There was nothing special about humans. Nobody, least of all humans themselves, had any inkling their descendants would one day walk on the moon, split the atom, fathom the genetic code and write history books. The most important thing to know about prehistoric humans is that they were

insignificant animals with no more impact on their environment than gorillas, fireflies or jellyfish.

For the same reason that our kids can't imagine a world without Google, Amazon and iPhones, we can't imagine a world in which we have not been a privileged species right from the start. Yet we were just one species of smart, social ape trying to survive in the wild. We had cousins: *Homo neanderthalensis*, *Homo erectus*, *Homo rudolfensis*, and others, both our progenitors and our contemporaries, all considered human and with similar traits. If chimps and bonobos were our second cousins, these were our first cousins.

Eventually, things changed. About 70,000 or so years ago, our DNA showed a mutation (Harari claims we don't know quite why) which allowed us to make a leap that no other species, human or otherwise, was able to make. We began to cooperate flexibly, in large groups, with an extremely complex and versatile language. If there is a secret to our success—and remember, success in nature is survival—it was that our brains developed to communicate.

Welcome to the Cognitive Revolution

Our newfound capacity for language allowed us to develop abilities that couldn't be found among our cousins, or in any other species from ants to whales.

First, we could *give detailed explanations* of events that had transpired. We weren't talking mental models or even gravity. At first, we were probably talking about things for survival. Food. Water. Shelter. It's possible to imagine making a statement something like this: "I saw a large lion in the forest three days back, with three companions, near the closest tree to the left bank of the river and I think, but am not totally sure, they were hunting us. Why don't we ask for help from a neighboring tribe, so we don't all end up as lion meat?"[3]

Second, and maybe more importantly, we could also gossip about each other. Before religion, gossip created a social, even environmental pressure to conform to certain norms. Gossip allowed control of the individual for the aid of the group. It wouldn't take much effort to imagine someone saying, "I noticed Frank and Steve have not contributed to the hunt in about three weeks. They are not holding up their end of the bargain, and I don't think we should include them in distributing the proceeds of our next major slaughter."[4]

Harari's insight is that while the abilities to communicate about necessities and to pressure people to conform to social norms were certainly pluses, they were not the great leap. Surprisingly, it's not our shared language or even our ability to dominate other species that defines us but rather, our shared fictions. The exponential leap happened because we could talk about things that were not real. Harari writes:

As far as we know, only Sapiens can talk about entire kinds of entities that they have never seen, touched, or smelled. Legends, myths, gods, and religions appeared for the first time with the Cognitive Revolution. Many animals and human species could previously say, "Careful! A lion!" Thanks to the Cognitive Revolution, *Homo sapiens* acquired the ability to say, "The lion is the guardian spirit of our tribe." This ability to speak about fictions is the most unique feature of Sapiens language.... You could never convince a monkey to give you a banana by promising him limitless bananas after death in monkey heaven.

Predictably, Harari mentions religion as one of the important fictions. But just as important are fictions like the limited liability corporation; the nation-state; the concept of human rights, inalienable from birth; and even money itself.

Shared beliefs allow us to do the thing that other species cannot. Because we believe, we can cooperate effectively in large groups toward larger aims. Sure, other animals cooperate. Ants and bees work in large groups with close relatives but in a very rigid manner. Changes in the environment, as we are seeing today, put the rigidity under strain. Apes and wolves cooperate as well, and with more flexibility than ants. But they can't scale.

If wild animals could have organized in large numbers, you might not be reading this. Our success is intimately linked to scale. In many systems and in all species but ours, as far as we know, there are hard limits to the number of individuals that can cooperate in groups in a flexible way.[5] As Harari puts it in the quotation at the beginning of this post, “Sapiens can cooperate in extremely flexible ways with countless numbers of strangers. That’s why Sapiens rule the world, whereas ants eat our leftovers and chimps are locked up in zoos and research laboratories.”

Sapiens diverged when they—or I should say we—hit on the ability of a collective myth to advance us beyond what we could do individually. As long as we shared some beliefs we could work toward something larger than ourselves—itsself a shared fiction. With this in mind, there was almost no limit to the number of cooperating, believing individuals who could belong to a belief-group.

With that, it becomes easier to understand why we see different results from communication in human culture than in whale culture, or dolphin culture, or bonobo culture: a shared trust in something outside of ourselves, something larger. And the result can be extreme, *lollapalooza* even, when a lot of key things converge in one direction, from a combination of critical elements.

Any large-scale human cooperation—whether a modern state, a medieval church, an ancient city, or an archaic tribe—is rooted in common myths that exist only in people’s collective imagination. Churches are rooted in common religious myths. Two Catholics who have never met can nevertheless go together on crusade or pool funds to build a hospital because they both believe God was incarnated in human flesh and allowed Himself to be crucified to redeem our sins. States are rooted in common national myths. Two Serbs who have never met might risk their lives to save one another because both believe in the existence of the Serbian nation, the Serbian homeland and the Serbian flag. Judicial systems are rooted in common legal myths. Two lawyers who have never met can nevertheless combine efforts to defend a complete stranger because they both believe in the existence of laws, justice, human rights, and money paid out in fees.

Not only do we believe them individually, but we believe them collectively.

Shared fictions aren’t necessarily lies. Shared fictions can create literal truths. For example, if I trust that you believe in money as much as I do, we can use it as an exchange of value. Yet just as you can’t get a chimpanzee to forgo a banana today for infinite bananas in heaven, you also can’t get him to accept three apples today with the idea that if he invests them wisely in a chimp business, he’ll get six bananas from it in five years—no matter how many compound interest tables you show him. This type of collaborative and complex fiction is uniquely human, and capitalism is as much an imagined reality as religion.

Once you start to see the world as a collection of shared fictions, it never looks the same again.

This leads to the extremely interesting conclusion that comprises the bulk of Harari’s great work: If we collectively decide to alter the myths, we can relatively quickly and dramatically alter behavior.

For instance, we can decide slavery, one of the oldest institutions in human history, is no longer acceptable. We can declare monarchy an outdated form of governance. We can decide women should have the right to as much power as men, reversing the pattern of history. We can also decide all Sapiens must follow the same religious text and devote ourselves to slaughtering the resisters.

There is no parallel in other species for these quick, large-scale shifts. General behavior patterns in dogs or fish or ants change due to a change in environment, or to broad genetic evolution over a period of time. Lions will likely never sign a Declaration of Lion Rights and suddenly abolish the idea of an alpha male lion. Their hierarchies are rigid, primal even.

But humans can collectively change the narrative over a short span of time, and begin acting very differently with the same DNA and the same set of physical circumstances. If we all believe in Bitcoin, it becomes real for the same reason that gold becomes real. Thus, we can conclude that Harari's Cognitive Revolution is what happens when we decide that, while biology dictates what's physically possible, we as a species decide norms. This is where biology enables and culture forbids. "The Cognitive Revolution is accordingly the point when history declared its independence from biology," Harari writes. These ever-shifting alliances, beliefs, myths—ultimately, cultures—define what we call human history.

A thorough reading of *Sapiens* is recommended to understand where Harari takes this idea, from the earliest humans to who we are today.

77. The Anatomy of a Great Decision

Making better decisions is one of the best skills we can develop. Good decisions save time, money, and stress. Here, we break down what makes a good decision and what we can do to improve our decision-making processes.

Improving our decision-making abilities is a central goal at Farnam Street. Better decisions save time, money, and stress. While it's an investment now, in the long run, learning principles and developing a multidisciplinary lens that we can apply throughout life is a worthy investment.

As we have said before, a decision should not be judged solely on its outcome.

Sometimes good decisions produce bad results. A recruiting process that has resulted in mostly excellent candidates will still occasionally fail to weed out a bad fit. It is impossible to have perfect and complete information for all the variables involved. So we do the best with what we have.

Using a decision journal can move us to that place where we are consistently making better decisions. At its core, the technique of identifying and reflecting on process from beginning to end helps us achieve the two main qualities in better decisions:

1. Using principles, not tactics
2. Looking at a situation through a multidisciplinary lens

These qualities are what we need to improve over time. And in the same way compounding interest increases our bank balance, better decisions produce exponentially better results the more of them we make. Hard decisions today, made well, prepare us to make decisions more easily in the future.

When we look around, however, to see what we can learn from others who made great decisions, we often judge based solely on the outcomes. Whether a decision by a family member to buy Coca-Cola stock in the '80s, or Caesar to cross the Rubicon, we evaluate a decision as good based on how things turned out.

Evaluating decisions on outcomes prevents us from learning. We need to dive into a decision, cut it open and examine its parts. Regardless of what happened, learning how a decision was made is the place to find knowledge. So what does the anatomy of a great decision look like?

// Evaluating
decisions on
outcomes
prevents us from
learning. //

The Marshall Plan

After WWII, Europe was in ruins. Much of the infrastructure had been destroyed. Many people were starving, and had lost everything they possessed. Those systems we take for granted, but on which we rely daily—transportation, manufacturing, agriculture—had been devastated. The economies were essentially broken, and the countries that saw a lot of fighting had much to rebuild. But with what money? Many countries were in serious debt. Continued, widespread economic hardships were on the horizon.

In 1947, Secretary of State General George Marshall put forward a plan that has since carried his name, a plan to give a massive amount of money to several European nations. Those countries accepted, the continent was rebuilt, and Marshall is credited with one of the most positive defining acts of economics, politics, and ethics in the last century. But when you look at the thinking that went into the Marshall Plan, the reasoning behind the details, you see that it would have been a great decision regardless of the outcome.

Asking the Right Questions

At the beginning, participants asked questions. What do we want to achieve? What problems are we addressing? What does a successful outcome look like?

From there came the principles, things like: strong economies minimize social unrest; countries that work toward mutual goals are less likely to fight each other; let's not have another war in Europe anytime soon.

Starting from these principles, decision makers evaluated the situation through a multidisciplinary lens. Economics, politics, humanitarian responsibilities, historical and psychological factors—the plan sought to address issues on many fronts and took a wide perspective into account.

The plan was developed in the State Department of the United States. It was not the work of a single individual, and contributions from many people made it into the final version that Marshall fought for in Congress.

In the end, there were three key decisions made in terms of the structure of the plan:

1. To give, versus lend, the majority of the aid
2. To require the nations receiving the aid to work out how to allocate it
3. To invite Russia to partake

Using Multiple Lenses

The decision to give rather than lend the majority of the aid was the result of looking at the situation through economic, political, and humanitarian lenses. It was also a win-win.

Immediately following the war, the European nations had put significant effort into restarting their economies. But they were doing it with borrowed dollars, needing to import far more than they were capable of exporting. Many economies needed modernization, which was impossible to fund while paying for imports at the same time. Without full economic recovery in Europe, there was great danger of a recession, or even a second depression. Basically, Europe needed money.

But economies are also about people. It is people who produce and consume and develop the economy. So it wasn't just the countries that needed financial assistance, but the people in them. The designers of the plan knew that hungry, desperate people would only create more social unrest. They saw that if they didn't give the money to Europe they might very well have to spend it on national security as Europe fell apart.

And we can't discount the impact of the physical reality of the aftermath of the war that the liberating forces confronted—starving people, towns reduced to rubble. The case for humanitarian assistance was strong.

Letting the World Do the Work For You

The decision to have the participating nations allocate the aid among themselves was the answer to what the historical, political and psychological lenses revealed.

Many people felt that the approach to reparations after WWI was a significant impetus for WWII. The First World War had a similar effect on the economies and infrastructures of the nations involved. In 1918, angry at Germany, France and Britain had demanded huge sums of money. The problem was, it essentially crippled Germany economically, and caused a social and political situation that created enmity among the European nations. Many argue that it was this series of events that produced a situation in which Hitler could come to power.

The creators of the Marshall Plan were aware of this, and it was one of the elements that influenced the design of the terms. If Germany collapsed again, they might be fighting World War III in twenty years.

By asking enemies to work together and approve each other's share, the plan created a buy-in that defused much of the anger and animosity between the nations. Just a couple of years earlier they had been at war with each other. After sacrificing so much in both lives and money, it was natural that the various peoples were angry over both who started the war, and the many violent and destructive events that were enacted over those six years.

But the US decided to not take sides and extend the alliances of the war. The plan creators realized this wouldn't help fulfill the principles they had chosen to abide by. Europe working meant Europe working together.

Outcomes Over Optics

Inviting Russia to share in the aid was another important result of applying those political, historical, psychological, and humanitarian lenses.

The end of WWII marked the beginning of the Cold War. More nebulous by nature, starting a couple of years after the liberation of Europe and the dropping of the atomic bomb, this political climate would shape international relations for the next 40 years. The Marshall Plan took into account how best to navigate this complicated territory. Russia had been a valuable ally during the war, holding the eastern front and inflicting considerable damage on Hitler's efforts. But immediately post-war their actions demonstrated a desire to at least influence, if not control, the political structure of the world. Their version of communism was at direct odds with US democracy, and was thus considered a legitimate threat. Even though there was very little expectation that Russia would participate, and possibly even less desire to give them money, Russia and its allied countries were invited by both the US and the European nations to participate in the talks involving the implementation of the plan. They chose not to, and followed up with accusing the plan of being a front to American imperialist goals. This was important because it forced Russia's hand. They could not later claim that the Iron Curtain was something that was thrust on them. It was, instead, something they deliberately chose to build.

The Marshall Plan is remembered as a great decision, not strictly because of its outcomes—though it did contribute to the debatably successful reconstruction of Europe, it did not succeed in preventing the deterioration of relations with Russia—but because it was firmly grounded in principles that were identified and executed through a multidisciplinary lens.

78. Letting the World Do the Doing

By Freya Mathews

What is nature, and how are we to live *with* it rather than *against* it, as ecophilosophers enjoin? My own understanding of nature and of our proper relation to it is ultimately traceable to a metaphysics that could be broadly described as panpsychist, in that it attributes an internal principle, or subjectival dimension, to matter generally. I have explored such a metaphysic elsewhere, and do not propose to detail these studies here.² My purpose is rather to consider the implications of such a broadly panpsychist premise for specifically environmental approaches to 'nature'.

There have of course been innumerable answers to the question, 'what is nature?' (Rolston 1988, Brennan 1998, Seddon 1997). One of the most common has been that 'nature' denotes the domain of physics – either the physical universe in its entirety or the laws that undergird it. In this widest sense, nature will not be of particular interest to environmentalists, since such a nature cannot be threatened, and does not, on the face of it at any rate, stand in need of human protection or conservation. In what sense then is nature understood by environmentalists as in need of defence? It is often assumed that, in speaking about nature, environmentalists are referring to the domain of biology, the realm of living things – forests and swamps, for instance, or plants and animals generally, or wildlife in particular – since it is this biological realm which is clearly under threat from the engines of industry and the appetites of global markets today. However, where the cosmological definition is too wide, this strictly biological definition of nature will usually turn out to be too narrow for environmental purposes, since many environmental battles are fought over inorganic, or only partly organic, features of the environment, such as rivers, dunefields, caves, mountains and rock formations, as well as over organic systems.

What environmentalists in fact usually seem to have in mind, in their references to nature, is parts or aspects of the world which have not been created or unduly modified by human agency. Is this a tenable environmental definition of nature? Implied in the definition is a distinction between the artefactual and the natural. I however, like many others, would immediately question the validity of defining the natural in contrast to the artefactual in this way, on the grounds that, since human beings, as biological organisms, surely belong to nature, and since making things comes to us as naturally as eating and drinking do, our handiwork itself has as much a claim to be considered part of nature as the handiwork of spiders, insects and marine life does (Mathews 1996). Therefore to regard trees and rocks and animals, not to mention webs, hives, termite mounds and coral reefs, as falling within nature, and cars and ships and computers as falling outside it, is to over-simplify the issue.

However, there *is* a distinction buried within this over-simplification which does, I think, call for further investigation. This is the distinction between what happens when things are allowed to unfold in their own way, or run their own course, and what happens when, under the direction of abstract thought, agents intentionally intervene to change that course of events for the sake of abstractly conceived ends of their own. By 'abstractly conceived ends' I mean here not ends discovered through abstraction from the particular but ends constructed through reduction of the actual to a blank slate for the abstractly imagined possible. In this latter sense, abstraction, or as I shall characterize it here, *abstractiveness*, is a matter of finding one's starting point for a course of action in the realm of the abstractly conceived or imagined rather than finding it within the reference frame of the actual. From the point of view of this distinction then, nature might be

understood as whatever happens when we, or other agents under the direction of abstractive thought, let things be, while artifice is what happens when such agents redirect events towards their own ends. The radical environmental injunction to live with rather than against the grain of nature then translates into an injunction to *let things be*.

It should be pointed out that the distinction between processes under the direction of abstractive thought and processes which unfold of themselves does not coincide with the distinction between conscious and unconscious processes, or even living and non-living ones. That is, it is not a distinction between processes which occur in, or as a function of, consciousness, and processes which occur in, or as a function of, unconscious matter. All things, whether conscious or unconscious, living or non-living, have laws of their own unfolding. In the case of the non-living, these laws may be embodied in the physical and chemical dispositions of the things in question. In the case of living beings, they may reside in biological or instinctual dispositions, which may be described as their immanent telos or conatus.³ Even conscious beings such as humans are imbued with an underlying conatus, an inherent 'law' of self-realization which is not a product of our own reflection or ratiocination, but which already informs our instincts, reflexes, and other spontaneous responses.⁴

All these processes however, whether in ourselves or in the world, are capable of being re-routed by the interventions of agents under the direction of abstractive thought – which is to say, agents seeking to realize abstractly conceived end-states rather than unthinkingly following their own immediate impulses. Thus inorganic physical processes can be redirected by such intervention; the behaviour of organisms can likewise be so modified; and spontaneous impulses in human beings can be suppressed or sublimated by the interventions of the individuals themselves or by societies. At each level a contrast can be drawn between an undisturbed state of affairs, in which everything unfolds or behaves in accordance with its intrinsic dispositions or an innate conatus, and a state of affairs in which the dispositions of things are diverted by agents to produce end-states which match those agents' abstract ideals or imagined scenarios. The undisturbed unfolding of events may be described as 'natural', according to the present definition, and the intentional re-direction of such a course of events as 'artificial'.

The contrast between the natural and the artificial, drawn this way, though not absolute,⁵ is, I think, a significant and defensible one for environmentalists. For the primary aim of environmentalists is to protect the biosphere from the depredations of modern civilizations, and it is arguable that when all things are left to realize themselves in their own way, the life process will be assured, at least in the long term. This conclusion is supported by commonsense and evolutionary theory: 'nature knows best' because life has had countless millennia to adjust itself to terrestrial conditions. But in many ecophilosophies, this faith in the capacity of the life process to take care of itself rests on deeper metaphysical foundations, involving an attribution of purpose or intelligence to reality. My own argument for this position rests on a view of the world as constituting on the one hand a subjectival whole (the One) imbued with its own conatus, or impulse towards self-realization, and on the other hand a manifold of relatively self-realizing individuals (the Many), whose conative impulses generally intermesh to further the self-realization of the whole (Mathews 2003).

To affirm the view that nature knows best is not to deny that when things are left to their own devices, the interests of individual organisms and smaller-scale ecosystems might not be subordinated to those of greater ecosystems or the biosphere as a whole: competition, predation and disease may further the ends of the greater systems at the expense of the smaller ones. But by and large, when the Many are following their own innate individual

patterns or principles of self-realization, the self-realization of the One is assured. If this is accepted, then to allow the Many to unfold in their own distinctive ways is presumably the surest approach to the protection of life on earth.⁶

How different is the outcome when agents under the direction of abstractive thought take control of events however. In accordance with their abstract ideas, such agents may make arbitrary interventions: they may kill off a particular species for the sake of its coloured feathers, for instance, or pollute a lake with manufacturing dye for the sake of people who have decided they want purple hair. With our powers of abstractive thought we can conjure up inexhaustible numbers of ways the world could be, ways ranging from the demonic to the absurd and whimsical through to the humanitarian or utopian; and with the same abstractive powers we can, increasingly, devise means for making the actual world conform to our fantasies, at least in the short term.

Historically speaking, abstractive thought has developed hand in hand with civilizations dedicated to the remaking of the world in accordance with variable human interests, values, dreams and conceits. By 'civilization' here I mean that form of social organization that was initially characterized by a settled way of life involving both the building of cities and the practice of agriculture and animal husbandry. The salient feature of civilization as a form of life is, in this context, its refusal to live within the terms of the given, as earlier hunter-gatherer societies had by and large done. Instead, civilized societies sought to change those terms – they strove to re-shape the world to suit their own purposes. They imagined categories of possibility beyond the already manifest – new kinds and classes of things in addition to those already in existence: houses to provide shelter, for instance, and wheels for transport, and animals subdued into pulling the wheeled vehicles, and succulent leafy vegetables growing in neat rows right at the back door of the houses. In order to conceive of these new kinds and classes of things, it was necessary to abstract quite radically from the world as it was, to look beneath the appearances at the underlying structures, and then to imagine ways those structures could be reassembled. This kind of thinking involves a different level of abstraction from that of the hunter imagining a kangaroo roasting on the fire at the day's end. Hunters and gatherers seek to satisfy their material and spiritual needs and desires within the categories of the given. They carefully study all the subtle particularities of life's tides, and learn to swim intelligently with those tides in order to achieve their ends. Civilized societies, in contrast, seek to transcend those particularities – the various vicissitudes of fortune, the reversals of the seasons, the manifold burdens of the flesh – by remaking the world to their own design. Rather than swimming with the tides, they try to uncover the laws of hydrodynamics and gravitation, in the hope of re-orchestrating and maybe even abolishing tides.

At the level of self, latterday civilizations have involved the re-deployment of our instinctual self-realizing energies in the service of socially prescribed ideals of individual selfhood. Our intelligence has been harnessed to abstract self-images and self-stories rather than to the deeper imperatives emanating from our conatus. Instead of letting ourselves be, we compulsively make ourselves over to match external ideals, where this can result in all kinds of aberrations, from neurotic individualism to fanatical collectivism or patriotism.

At the level of both world and self then, civilization tends to induce a preference for the abstractly imagined over the given, and seeks to substitute the possible for the actual. This tendency of civilization has become progressively more pronounced in the modern period, with its repudiation of tradition and its exponentially increasing power to manipulate matter, until it has resulted, today, in the dizzying regime of international capitalism, involving almost incessant, runaway erasure of the actual in favour of the possible, a regime euphemistically going under the name of 'development'.

When human beings are freed from excessively abstract thought however, and restored to their conative nature, then the world is relatively safe from such 'development'. For the conative natures of all beings are, from an environmental point of view, relatively trustworthy, simply because, as I have already noted, all have evolved in concert with one another, with the consequence that their natures are mutually cross-referencing. Self-realization is achieved, at the conative level, within the parameters of the already existent rather than the merely possible, and thus, at a conative level, all beings have a broad interest in maintaining the world as it is.

To recapitulate then, when 'nature' is defined, as it has been here, in contrast with artifice, it is arguable that generally, on the terrestrial scale, though not perhaps in every conceivable circumstance, nature knows best. By this I mean that when things are left to themselves, the biosphere is likely to fare better than it is when things are subject to our arbitrary interventions. There will of course be casualties at the level of individuals and smaller-scale systems when things are left to unfold in their own way, and as beings with a constitutive interest in our own self-preservation and the preservation of our nearest and dearest, we are on occasion called upon to intervene in these unfoldings, just as hunter-gatherers do in the course of their daily lives. Such interventions will not count as arbitrary however, and will be compatible with a general attitude of letting things be, an attitude which renders the overall project of life on earth relatively assured.

2. RETURNING TO NATURE

The trap for environmentalists, in thinking about nature, is to reify it, to conceive of it in terms of things rather than processes. When we think of it in this way, we understand it as consisting of all those things which are not the product of abstract human design: forests, swamps, mountains, oceans, etc. We then contrast nature with the human-made environment, consisting of cities, artefacts, technologies, etc. We make the same mistake in thinking about nature at the level of the self: the *natural* self is equated with the body, the instincts, intuitions, emotions etc, and this is contrasted with the civilized self, consisting of the controlled rational ego. The environmentalist's defence of nature is accordingly read as a project not only to save existing swamps, forests, etc, but to restore lost ones. Introspectively it is taken to imply a counter-cultural ethos of spontaneity, intuitiveness and instinctuality. From the present point of view, this is a mistaken reading. To 'return to nature' is not to restore a set of lost things or attributes, but rather to allow a certain process to begin anew. This is the process that takes over when we step back, when we cease intervening and making things over in accordance with our own abstract designs. Such a process can recommence anywhere, any time. It is not logically tied to those aspects of the world that we mistakenly reify as nature – the forests, swamps, instincts, bodily functions, etc – but can start to unfold again in the midst of the most intensively urbanized and industrialized environments on earth and in the most controlled and civilized of persons.

In a world already urbanized, 'returning to nature' means not tearing down the cities and factories, and planting woods and gardens in their stead. Such action would merely perpetuate the cycle of making the world over in accordance with abstract designs – albeit in this case ecological designs – and would reinforce the mind-set involved in living against nature. Rather, 'returning to nature' in an urbanized world means allowing this world to go its own way. It means letting the apartment blocks and warehouses and roads grow old. Yes, we shall have to maintain them, since we shall need to continue to use and inhabit them. Inhabitation will also call for adaptation and aesthetic enhancement. But this is compatible with a fundamental attitude of letting be, of acquiescence in the given, and of working within its terms of reference, rather than insisting upon further cycles of demolition

and 'redevelopment'. Gradually such a world, left to grow old, rather than erased for the sake of something entirely new, will be absorbed into the larger process of life on earth. Concrete and bricks will become weathered and worn. Moss and ivy may take over the walls. Birds and insects may colonize overhangs and cavities within buildings. Green fingers will open up cracks in pavements. Bright surfaces will fade, acquiring natural patinas. Under the influence of gravity, the hard edges of modern architecture will soften, and imitate the moulded contours of landforms. Given time, everything is touched by the processes of life, and eventually taken over by them, to be fed into the cycle of decay and rebirth. Left to itself, the living world reclaims its own. Things which initially seemed discordant and out of place gradually fall into step with the rest of Creation. Old cars take their place beside old dogs and old trees; antiquity naturalizes even the most jarring of trash.⁷

When the world is allowed to grow old, when things are retained, or left to unfold in their own way, then it is possible truly to *inhabit* places, to come to belong to them, in ways that are undreamed of in change-based societies. As years pass, and places retain their identities, they can, if we let them, come to be inscribed with our histories and the histories of our families and communities. They acquire meaning for us as our life experiences are woven into them. Here, on this road going down to the creek, where I walk my dog every week, is the house my great grandfather built. I have a faded photograph of it on lock-up day, sometime late in the 19th century. Around the corner is the store my grandfather ran, and over there is the park in which my parents walked, each evening, holding hands, for sixteen years. Here, alongside it, is the cemetery where I roamed in my gothic youth, looking for the grave of that same great grandfather, keeping trysts in the peppercorn groves, composing poems about roses. And it was along the tree-lined avenue at the edge of this cemetery that I pushed my baby son to creche. Layers and layers of significance accrete as our lives unfold amidst familiar spaces, significance that can for us never be reproduced in any other setting. The setting itself infiltrates our identity. This irreplaceable significance of our own place or places for us binds us to them. We become their natives.

This belonging is reinforced in another way when we let our world – whether urban or rural – grow old. For when the lay-out and structures and constellation of physical features that define a particular place are allowed to endure for a long time, then not only can it become interwoven with our individual and collective identity in a way that binds us to it, but, from a panpsychist point of view, *it* can come to know *us*. In time, and only in time, a place can, if we commit to it, come to accept us, open its arms to us, receive us – it agrees to be our place, attentive to us, attuned to us. We become its people. The land, or place, claims its own. It can never receive the casual or expedient sojourner or stranger in such familiar fashion. In this way too then, through time, and the reinhabitation of places that are allowed to be, we become native to our world.⁸

The self-realization of the biosphere – which is to say, the unfolding of nature on earth – involves a pattern of gradual but continuous change – a pattern of aging and decomposition followed by spontaneous reconstitution into new forms. This is what happens to things when we let them be. Artifice, as here understood, correspondingly consists in any regime of abrupt, wholesale change, change that involves the erasure of one environment, or order of things, and its replacement with an entirely new one. Such regimes generally come about only at the instigation of agents in the grip of abstract ideas or images which they are intent on actualizing irrespective of context – irrespective of what existed before and what surrounds the new 'development'. In this sense an old factory site, overlaid with grime and saturated with heavy metals, but in its cracks and neglected crannies also burgeoning with hardy and creative biological and social forms of life, is

more natural than a town planner's lush park stocked with store-bought indigenous plants and subject to wholesale redesign or 'redevelopment' at any time.

I should note here that by making the point that 'nature' in its deeper sense connotes not trees and grass and wildlife, but the processes which occur to any and all things when they are no longer subject to the interventions of agents under the influence of abstractive thought, I am by no means wanting to say that the conservation of trees and grass and wildlife – which is to say, environmentalism in its traditional form – becomes superfluous. Existing ecosystems should, like cities and selves, be allowed to unfold in their own way, free from undue human disturbance. Where such ecosystems have already been modified by the introduction of exotic species however, the application of the principle of letting-be is more complex. One might on the one hand infer that the new and old species should in principle be left to sort the conflict out themselves. To respect nature in this situation may not imply that we should eradicate the exotics and restore the indigenous. It might mean that we should forego interventionist "management" and allow natural processes to reassert themselves, however distressing it might be to watch native plants and animals disappearing under the onslaught of aggressive invaders. Such stepping back is, according to one reading of the principle, the course that would allow for a true "return to nature": some of the original species would presumably decline, and new ones would steal their niches, but as soon as competition had stabilized, speciation would begin again in situ, because we would no longer be intervening to reverse this trend.

However, in situations in which custody has properly been assumed by one party for another, it might seem that a balance needs to be struck between the attitude of letting-be, on the one hand, and due responsibility, on the other. The attitude of letting-be must not be allowed to degenerate, when applied to living systems which have already been annexed into our care, and deprived of their own conativity, into mere neglect, an ethos of letting-die. In the next section I shall suggest modalities of proactivity that would to a degree enable us to protect and preserve not only ourselves but other species and lands in a manner consistent with the principle of letting-be.

A certain stepping back, then, is what is involved in 'returning to nature' in the outer world. At the level of self, making the transition from civilization to a more natural state is no more a matter of trying to reinstate an instinctual, free-and-easy, impulsive regime than returning the world to nature is a matter of restoring lost forests and swamps. To try to transform the tensed, guarded, rationally-minded self of civilized society in this way would only be to perpetuate the process of control – the process of making the self over to match a socially approved ideal. At deeper psychic, and perhaps somatic, levels, such an attempt, with the self-rejection it implies, would presumably only exacerbate the tension to which the self in question is subject. The way for a self-censoring self to 'return to nature' is simply for it to stop altogether the business of attempting to make itself over in accordance with abstract ideals, and surrender instead to what it already is. When we give up being dissatisfied with ourselves, and reconcile ourselves to our 'unnaturalness', our tedious up-tightness, for instance, then, ironically, we start to relax anyway; as we stop forcing ourselves to follow the latest social prescriptions, our own instinctual conatus has a chance to make itself felt again. Gradually we become re-animated with our native will to self-realization.

I am not suggesting here, by the way, that continuing to be repressed and civilized does not itself require effort. Clearly it involves enormous effort. But since this is a form of effort to which we may already be habituated, it is not likely to be as great as the effort that would be required to convert our entire system of response to a more spontaneous, impulsive mode. Nor am I suggesting that the self animated by its own conatus is a passive, nothing-is-worth-the-effort kind of self. Conatus in humans, as in other animals,

involves quantities of striving. People will go to great lengths to find food to satisfy their hunger, for instance. They will expend themselves utterly in sexual activity. But these are exertions that the organism *wants* to perform – the effort is made with rather than against the grain of its innate desire. In this sense it is no effort for the organism to make such an effort, whereas the effort required for an organism to act against its innate tendency, in favour of socially prescribed ideals, for instance, is immense.

At the level of both self and world then, it is never too late to return to nature. No matter how artificial our self or world has become, they can always, at any given moment, become subject again to natural processes, simply by our decision to call a halt to 'development' and 'progress' and 'self improvement', and to allow things to remain as they are, to be retained rather than replaced. In saying this I am not of course intending to ban change altogether, but to insist that change should not disrupt the general unfolding of things. It should not raze the old and superimpose on the space that is left something unrelated to what preceded it. Change should carry us gently and smoothly into the future, respecting the cycles of creation, decay and regeneration. It should grow from within the shell of the given.

It might be objected at this point that the attitude of letting things be that I am recommending here is too passive to be of use to the environment movement, that in the end it amounts to little more than a laissez-faire acquiescence in the political status quo. To dispel this fear, let me explain in a little more detail how such an attitude would, if adopted by a significant proportion of the populace, in its quiet way thoroughly disable the present world-destroying order of capitalism, by systematically negating the following values on which that order rests.

Consumerism. When we embrace those things that are already at hand, we do not seek to replace them with new ones. Such embracing of the given is thus an antidote to the culture of disposability and conspicuous consumption fostered by capitalism. From the viewpoint of letting things be, we would be most pleased, not with our brightest and newest things, but with those that were our oldest and most well-worn, things which had long figured in our lives, and mingled their identity and destiny with ours. 'Keeping up with the Joneses', if it applied at all in the letting-be scenario, would entail having fewer and older things than the Joneses. (Of course it would not apply, since in the new scenario we would not be measuring ourselves against the kind of social expectations personified by the Joneses.) Acquisitiveness, and hence consumerism, melt away in the face of an attitude of letting be.

Commodification. When we value things and places for the meaning that our own lives have invested in them, via our relationship with them, this removes them from the market place. They cannot be replaced by other things and places, even things and places of the same type, since the substitutes will not share our history nor hence be imbued with the same meaning for us. From this point of view, I could no more buy or sell things or places which had become part of the landscape of my life, part of my very identity, than I could buy or sell members of my family. Thus the pool of commodities is continually diminished.

Productivity. When we embrace the world as it is, and are no longer forever seeking to make it better, according to abstract (generally egocentric or anthropocentric) conceptions of the good, then greed is effectively abolished. We no longer crave bigger and better houses, cars, roads, cities, whatever. We are instead attached to what is already given. There is thus no call for ever-increasing productivity.

Progress. When people no longer believe that the world can always be improved, the slate wiped clean and a better world, a better society, inscribed on it, then the ideological

rationalization for capitalism viz that it can continue to improve peoples' 'standard of living' indefinitely, collapses.

Efficiency. In late capitalism, efficiency – patently a notion pertaining to means – has acquired an almost fetishistic status. Tools (where this includes all kinds of techniques and procedures as well as implements and technologies) are valued not so much for what they do as for their efficiency, and they are retained only so long as their efficiency is perceived as maximal. When the attitude of letting be is assumed however, tools are valued not merely for their efficiency, but for their meaning. I may continue to use an old plough, or a leaky fountain pen, or a certain laborious method for making dough, simply because this is the plough, or pen, or method, that my mother or grandfather used. Efficiency may still be a consideration, but it will be only one factor determining the means I choose to achieve my ends.

Industry/business. These are the two definitive modalities of capitalism – industriousness and busy-ness – both connoting a certain kind of externally driven, externally focussed, hectic state of doing or acting. Those who are busy and industrious act on the world, they take initiatives and make things happen. When we assume the attitude of letting be however, we let the world do the doing, and we fit in with it. We favour 'inaction', in something like the Taoist sense of this term, which signifies not passivity, but action which is effortless because emanating from our own conatus and meshed with the conatus of other beings rather than driven by external social expectations or ideologies.

Development. When we understand 'development' in terms of the transformation and regeneration that eventually transpires when things are left to grow old, to unfold in their own way, then we will not tolerate the erasure of the given which is the precondition and prelude to 'development' in the capitalist sense ie the replacement of the given by the decontextualized abstractly imagined new.

Profit. If we do elect to let things be, it is on the assumption, as I explained earlier, that nature knows best – that nature, left to itself, conserves itself, does not exhaust itself, but rather replenishes itself, in accordance with the law of birth, decay and rebirth. To sustain itself in this way, nature returns *everything* to the life cycle, it recycles everything. There is no 'surplus' in this system, and hence no accumulation. The law of return makes nonsense of the notion of 'profit'. 'Profit' in one part of the system merely signals loss and depletion in another part.⁹

Automation. For the capitalist, labour is merely a means to production; if automation provides a cheaper, more efficient means, it will be preferred. From the viewpoint of letting things be, human labour is, or can be, a vehicle for meaning. Things become significant to us partly as a result of our building, making, repairing or decorating them ourselves. How much more of a presence in our lives is a church – like the Russian Orthodox Church in my neighbourhood – which is built by the hands of the parishioners themselves, over a period of many years, than one which is contracted out to professional builders and erected 'efficiently' in eight weeks. To 'mix our labour' with things is, as Locke said, though with entirely different intent, to make them ours, in a sense analogous to that in which our family is ours. To make things ourselves, or to have them made by the hands of others, then, is in certain respects preferable, from the present point of view, to mechanization of the processes of production.

Property. When people honour the world as it is – honour its immanent telos, its capacity to unfold in its own way – they no longer seek to *own* the world, but rather to *belong* to it. They belong to their world by being faithful to the things it contains, keeping and tending

them and letting the world manifest through them as they endure. The world expresses itself, reveals itself, through the changes it induces in these things, through the lichen on the walls, the cracks in the glaze, the slow, stooping, inevitable return to earth. By continually replacing things we never witness the way the world reclaims its own, so we miss out on knowing it, encountering it. Strangers to the world, we do not belong, we are anything but natives. We comport ourselves as invaders, conquerors, buying up the matter which means nothing to us, and trashing it when we are tired of it. We treat ourselves, our own bodies, in the same way, truculently professing to own them and reluctant to allow them to be reclaimed by the world, reluctant to see the world tenderly revealing itself to us through them, through the fading and crazywork and mute surrender of flesh to gravity. But of course, at the final call, the world claims us anyway, and we go, back into the earth, but no wiser, and a lot lonelier, strangers to the end.

To assume a panpsychist worldview, and to express this worldview via an attitude of letting be, is thus inevitably to extricate oneself, to a significant degree, from the ideological grid of capitalism. It is to begin to shift towards an entirely different form of praxis and of management of the material dimension of life – in other words, to an entirely different ‘economics’, or way of ensuring the satisfaction of our material wants and needs. Since economics involves a certain engagement, on our part, with the world of matter, an economics with panpsychist presuppositions will obviously differ from an economics based on a mechanistic worldview. For when the material world is viewed as a subject, or as a manifold of subjects, then economics constitutes an opportunity for encounter: the ways in which we utilize matter must not conflict with, but enhance, our intersubjective engagement with it. The basis of an economics structured in accordance with the principle of letting-be will be briefly sketched in the next section.

From a panpsychist perspective, respect for nature, as we have seen, is not a matter of protecting only ecosystems, but *all* material things, from undue human disturbance, including things that do not usually arouse the concern of environmentalists, even non-anthropocentric environmentalists, such as deep ecologists. This view of nature, and what it is to live with rather than against it, implies an ethos that is far more encompassing than that of the traditional environment movement. It is an ethos as encompassing in fact as the ethos of modernity that it seeks to reverse. For the hallmark of modernity is radical change – in the form of development, control, management, design, intervention, progress, improvement, even salvation. (This is reflected in the very etymology of the word, ‘modern’, which is derived from ‘mode’, meaning ‘of the present’, as in ‘à la mode’, keeping up with the latest. Modernity is that period which can be characterized in terms of its commitment to the ever-emerging new, its dissatisfaction with the given, its radical discontinuity with the past and its dissociation from tradition.) The ethos of letting be challenges modernity head on, trusting as it does the innate wisdom of things, and eschewing as it does the definitive ambition of modernity, to remake the world in accordance with abstract ideas. From the present point of view, not only is environmentalism, even in its deep-ecological forms, missing the larger metaphysical picture in its approach to modernity; it is also itself deeply entangled or imbued with the modernist ethos in its understanding of its own mission; it needs to extricate its legitimate concern for nature from heroic modernist assumptions about its own world-changing, world-saving role.

I am suggesting that instead of perpetuating this profoundly modernist ethos of changing or saving the world, the environment movement could assume an attitude of letting things be. We could step right outside the presuppositions of modernity, and dare *not* to try to make things better, at any rate if ‘making things better’ is a rationalization for continually

replacing one regime with another. When we say, 'let's fix the world up – let's pull down these slummy old tenement blocks and build a brand new eco-permacultural-urban-village in their stead' – we are just as much in the grip of the old ethos of domination and control as the city fathers were. We are rejecting the given in favour of an abstract or imagined alternative of our own – we are refusing to 'let things be' – and it is this hubristic mentality which is the motor of modern civilization and the source of the environmental crisis. In remaining in the grip of the old ethos, in nursing the desire to make things better, we are simply continuing to water the deeper modernist roots of the present predatory economic system.

An ethos which tries to avoid the pitfalls of this mentality will, of course, be an ethos of conservatism rather than radicalism. This conservatism has always been implicit in the environment movement, as plainly betokened by the fact that the term 'conservation' is often regarded as synonymous with 'environmentalism'. However, such conservatism does not imply that the attitude of letting be is aligned with the political right. The political right has historically, of course, been conservative, that is, committed to the given, while the left has been opposed to the given, and committed to the abstract possible or ideal. The historical right however, though conservative, differed from the present position inasmuch as it was socially rather than ontologically motivated – it was at heart a defence of social, political and economic privilege, rather than a defence of the world for its own sake. In other words, the right insisted on the preservation of traditions and institutions because it was through these traditions and institutions that the upper classes retained their privileges. A degree of ontological conservatism – the conservation of architecture and landscapes, for instance – was implicit in this position, but this ontological conservatism was in reality a mere spin-off from a self-interested politics of oppression. The historical left rejected this politics of oppression, and demanded the overthrow – and ongoing readjustment – of the existing social order, in order to end the systematic privileging of the powerful few at the expense of the many. This revolutionary or radical politics however sustained an unremitting antagonism not only to traditions and institutions, but to the world that these traditions and institutions had built, and this legacy has served, in the long run, to legitimate a rapacious contempt for the given in all its social and ontological forms, where this contempt is the hallmark of late capitalist modernity.[10](#)

The attitude of letting things be, in contrast, is conservative out of genuine respect for the world, for the capacity of things to unfold in their own way. Its conservatism is ontologically rather than socially motivated, and it extends primarily to material things rather than to cultures, traditions and social institutions. This attitude certainly does not spring from a desire to preserve the privileges of the few, as that of the historical right has done. Indeed, it tends, almost incidentally, towards a de facto form of non-hierarchism, inasmuch as it is antithetical to the accumulation of wealth, as I have explained above. It achieves this 'equalizing' effect, however, without recourse to the radicalism, to the ethos of intervention and overthrow, of the historical left. So, without itself resorting to the ideality of morality, the ethos of letting be reconciles something of the custodial role of the right with something of the moral intent of the left. In this respect it is in fact the reverse image of the market-driven politics which is achieving hegemony in the industrialized world today, and which is also neither of the left nor the right. This latter politics – the new 'economism' – combines the old rightwing investment in the perpetuation of minority privilege, and moral indifference to the suffering of the majority, with the old radicalism of the left, its dissatisfaction with the given, and its dedication to building ever new, ever more extravagant, worlds. In other words, 'economism' has managed to combine the downsides of both the right and the left. In this unholy new regime, nothing is sacred, everything – every being, every object, every place, every institution, every element of culture and

society, every relationship – is subject to obliteration or co-optation by a commerce that sustains fewer and fewer. The attitude of letting things be effectively inverts this nightmare and, by stepping outside the game of left and right altogether, inadvertently combines the essence of the upside of each of the old right and left.

3. AGENCY IN A SYNERGISTIC MODE

To many people concerned about the fate of the global environment, the principle of letting-be, as here outlined, may still appear unduly quietistic. How are we to wrest a living from the world without subordinating its ends to ours? How are we to address environmental degradation and the loss of ecosystem integrity caused by human intervention if we simply step back and let things take their course? How are we to defend our world and all its human and other-than-human inhabitants against those with the political will and muscle to oppress them if we merely acquiesce in the given, and decline to take up a posture of resistance? Yes, the attitude of letting-be may represent the deepest challenge that can be issued to the mindset of modernity, but if it does not also prescribe positive modes of agency it must ultimately be self-defeating.

However, the principle of letting-be is not, as it turns out, entirely inconsistent with certain modes of proactivity, including modes of resistance. The modes of proactivity in question are those that work with, rather than against, the grain of the given. By this I mean that there are forms of action that achieve their ends by engaging with pathways of energetic flow and communicative influence already at play in the world. An agent in this mode is a kind of metaphysical hitchhiker, catching a ride in a vehicle that is already bound for her destination. Or, more usually, via the hitchhiker's communicative engagement with the driver of the vehicle, both the hitchhiker's own plans and those of the driver are changed. The vehicle heads for a destination that neither hitchhiker nor driver had previously entertained, but which now seems more in accordance with their true will than either of their previous destinations.

The hitchhiker lets things be in the sense that she does not seek to turn back processes and conative unfoldings already in train. Her mode of proactivity, in seeking her own conative fulfilment, is through engagement with these existing unfoldings. It necessarily follows that the matrix of these unfoldings sets limiting conditions on her agency: she does not entertain ends or means defined outside the reference frame of the already given. This is a mode of agency that I have elsewhere termed *synergy* (Mathews, 2003). In synergistic mode, the agent can pursue ends of her own, and can even seek to transform the status quo, but not by abstracting from the given, and trying to replace it, holus bolus, with an arbitrary design of her own. She does not seek to erase the given, or contradict it, but by joining her own conativity to its she elicits from it a new response, a spontaneous unfolding in a new direction.

Let's consider, in briefest outline, how a synergistic mode of agency would operate in the economic, environmental and political contexts foreshadowed in the questions posed at the beginning of this section. These examples of synergistic agency are intended merely to illustrate the manifold possibilities for activity consistent with the principle of letting-be. They are not put forward as themselves a design for an alternative society!

Economics in synergistic mode. Extractive economics, based on the inactivation, the rendering inert, of "natural resources", can readily be reformed along synergistic lines; mutualistic partnership with animate natural processes then replaces the inactivation of those processes, their subordination to our ends. Such synergistic possibilities have already been extensively explored in the literature of alternative economics under the

rubric of sustainability. Prime examples of synergy in this context are the alternative energy industries, employing techniques for harnessing energy from renewable sources; wind and sun, for instance, are not diminished or denatured by being temporarily diverted to serve our purposes. Windflows and lightflows are tapped without basic meteorological and solar patterns being fractured. (Water, though a renewable source of energy, is more problematic in this context: diversions and dammings of water often do result in the death of rivers.)

The ecological disposal of “waste” is another example of synergistic praxis. Much of our productive activity could be conceptualised ecologically as accessing elements and energies (“resources”) not otherwise available to ecosystems, then, incidentally to our productive intentions, converting them into forms available for re-use by other species. Like nitrogen-fixing plants, whose metabolism benefits the entire ecological system, the side effects of our productive activities could vastly enhance rather than diminish the biosphere.¹¹

Similarly, primary industries such as agriculture and pastoralism could be organized with a view to their potential for enhancing rather than degrading the environment. Pastoralism has brought water, in the shape of wells, to the arid rangelands of Australia, for instance, and has hence enhanced conditions for wildlife there, though the introduction of exotic grazers and browsers has at the same time in other ways diminished ecosystem integrity. But there is no reason why a pastoral agenda could not bring net benefits to these lands, if pastoralism were conducted on synergistic lines. Provision of water together with the judicious harvesting of certain wild species rather than the husbanding of domestic ones, for instance, could possibly lead both to positive ecological outcomes and to an increase in profitability for pastoralists.¹² Similar possibilities are well recognized, though little practised, in agriculture: hedgerows and wildlife corridors restore lost habitat while providing refuge for insectivorous birds and mammals that control crop pests. Even more directly, authorities are now suggesting that farmers be encouraged to produce environmental goods, such as pollen, in addition to traditional crops, as the economic value of environmental goods is finally being recognized and factored into production.¹³

Environmentalism in synergistic mode. Where ecosystems are disrupted or degraded as a result of human intervention, the principle of letting-be may, on the face of it, seem to require that we step back and allow things to take their own course, even if this entails species loss or ecological damage. In this case however, as noted earlier, the principle of letting-be could degenerate into a rationale for neglect. Is there a third, synergistic way between outright interventionism and mere letting die? Such a way does exist, I believe, and it can be characterized as the way of environmental *healing*. Healing, in a synergistic sense, would involve not mechanistic intervention – the substitution of new parts or suites of species for old – but the reactivation of a system’s own conative energies. Healing draws upon forces or powers already present within the existing state of things to restore the system in question to dynamic equilibrium. Healing represents a synergistic approach to human as well as to ecological illness and malaise. In the human case, it consists not in the prolongation of life by way of mechanical life support systems in patients whose own conativity is terminally impaired, but rather in the strengthening of conativity – the boosting of the immune system, for instance – in cases where such strengthening is still achievable. In the case of ecosystems, healing might consist in the replenishment of exhausted soils or the removal of exotic organisms to enable the ecosystemic impulse towards biodiversification to be maintained. The wholesale “restoration” of an original suite of species however would constitute interventionism rather than healing.

It might be asked, however, whether exotic organisms, or feral species generally, can be removed from susceptible environments, or whether their impact on these environments can be diminished, without recourse to strategies that violate the spirit of letting-be. Can such removals or reductions be effected synergistically rather than in the typical dominate-and-control modality of environmental management? Synergistic strategies in this connection will presumably have to mesh the fate of exotics and ferals with the conativities of the ecosystem in which they are located. They will, in other words, have to utilize the resources comprised by exotics and ferals to service the ecosystem. When situations involving exotics and ferals are viewed in this light, it often turns out that removal is not required. As Tim Low reports, “Foreign plants – weeds and crops – now feed and shelter millions of native animals, and even a few native plants. Exotic animals – especially rats, mice and rabbits – feed millions of natives too. A typical bird of prey, parrot or orchard swallowtail now eats foreign food. Many species now rely largely on alien tucker. If Australia’s foreign contingent vanished overnight, many ecosystems would be kicked into chaos.” (Low, 2002, p. 93) “Environmental management” is not necessarily, from this point of view, a matter of trying to reinstate pristinely indigenous biotic regimes but rather of evaluating environments on a case by case basis, identifying the flows – food chains and disease vectors and catalysing factors, for instance – and opening them up or closing them off to one another in ways best calculated to promote the further unfolding of ecosystems. Where a given feral invasion is demonstrably destructive to a particular local environment, and proves intractable in the face of local synergistic measures, the systemic frame of reference can be expanded to include human populations. It is these populations, after all, that are placing the greatest pressure on global ecological systems, and if vital needs of human populations can be satisfied by harvesting exotics or ferals –for food, for instance, or fertilizer – then to that extent exotics or ferals are reintegrated back into the larger system. They supply a demand that would have been made anyway, so that redeploying them to this end prevents further pressure being placed on the larger ecosystem. In other words, the problem of feral invasions can often be solved by us in the simplest of ways: *by eating the ferals*.

However, to propose this synergistic solution to the problem of feral invasions returns us to the discussion of economics. Environmentalism in a synergistic mode cannot always be grafted onto an economic system that is still organized along dominate-and-control lines. To implement the above synergistic solution to the problem of exotics and ferals in any systematic way would call for major adjustments to our economic arrangements. Our system of production and consumption is rooted in the same kind of agrarian civilization of which the abstractive mentality, which seeks to adapt the world to our needs rather than adapting our needs to the world, is an expression. The abstractive mentality, as outlined earlier, abstracts altogether from the actual in setting its goals: it erases the actual in favour of the abstract possible. It entertains abstract ends as *idees fixes*, which it pursues regardless of cost or context. Both production and consumption in modern societies follow this pattern. Agricultural centres or manufacturing plants are established on permanent sites to produce specific products that have generally originated abstractly in market researchers’ imaginations and then become fixed in consumers’ expectations. Primary industry insists on producing lamb, for instance, in spite of the fact that the countryside is teeming with feral goats, rabbits and camels; this *idée fixe* is then imparted to the consumer, who expects lamb for Sunday lunch and will not countenance the idea of roast feral.

Modern producers and consumers are in this sense still agrarian at heart: they decide what will be produced and what will be consumed well in advance of discovering what is actually on offer, what is already available in their local environment. They

are *makers* rather than *finders*, preferring their own version of reality to reality as it is given. All the infrastructure of production reflects this outlook. Both production and consumption could however be geared along the lines of finding rather than making. Production infrastructure could be designed for assembly and disassembly and hence for mobility as well as for flexibility of output, and consumers could develop a taste for the given, in all its unpredictability, rather than for the ideally prescribed.

Of course, an economics of the given such as this would have to conform to the general or overarching principle of synergy if it were not to become merely another excuse for environmental rip-off. After all, the availability of native forests has not been overlooked by modern societies, and native forests have consequently been consumed to the point of obliteration. The same fate could await not only ferals but native wildlife if the ethos of utilizing the given were followed without caution and due regard for the larger principles of synergy and letting-be.

Politics in a synergistic mode. It was noted in the previous section that if everyone assumed an attitude of letting-be, then the consumerist motor of capitalism would stall and the progressivist thrust of modernity subside. Indeed, ideologies of oppression – oppression on grounds of sex, race, class, age, sexual preference or species membership – would crumble in the face of a generalized respect for the conativity of things. But in reality it is not the case that everyone has assumed, or ever will assume, an attitude of letting-be. On the contrary, modern societies are profoundly committed to taking charge of things, to manipulating the world so that it serves sectorial human interests rather than ends of its own. Wouldn't following the principle of letting-be, in the context of this political reality, amount merely to leaving everything as it is, abandoning the world to those whose goal is to appropriate and exploit it? In other words, the principle of letting-be seems to afford no possibility for *resisting* the political status quo, where that status quo is a function of a systematic inversion of letting-be itself. In a political context then, the principle seems self-defeating: in deference to it we are required to step back and allow regimes of cooptation, which obstruct and divert the general unfolding of things, to prevail.

It is important to note here that the principle of letting-be does not apply to ideas, ideologies or discourses in their own right. Our reason for letting things be is that they are imbued with a conativity of their own; left to themselves they take care of themselves and in taking care of themselves they promote the self-realization of the systems that constitute them. Clearly this is so only in the case of embodied things, things that are elements of the concrete, corporeal world. It makes no sense to ask of abstract things – ideas, ideologies, discourses – that they take care of themselves. But when ideas, ideologies, discourses are operative in society – as institutions, customary practices, cultural attitudes – then they are implicated in real, embodied entities. In other words, as we find them in society, ideas, ideologies and discourses are not merely attenuated abstract entities, but ride on the back of actual individual and collective conativities. In addressing discursive aspects of society then, we are engaging with these conativities, and in this sense we are indeed negotiating the concrete, corporeal given. The principle of letting-be accordingly comes into play.

So what is the advocate of letting-be to do in the face of institutions and practices that contradict her principle? Once again she must try to hitch a ride with the very forces that offend her, giving them their due as (possibly distorted) instances of conativity, but trying, by engagement, to induce them to flow towards a place of true conative increase rather than diminishment. So, for instance, confronted with sexist discourse, the advocate of letting-be will not confront but nor will she merely acquiesce. She will try to use sexism to transcend sexism. To the extent that sexism is legitimated by an ethos of masculine superiority, she might represent masculinity as an ideal of worthiness rather than of

violence, so that men will measure up as most masculine, most manly, not when they are abusing women but when they are most respectful of them. Similarly with racism. Our advocate of letting-be might try to transform the ideal of white superiority into an ideal of justice, equality and reason, the liberal virtues of the Western enlightenment, so that people will never qualify as more white than when they are respecting the rights of others. Militaristic impulses can be harnessed to the goals of peace by converting military forces into peace-keeping forces, thereby putting courage, valour and strategic acumen to good use. When conflicts between parties of different ideological or religious persuasion break out, one party can seek peaceful resolution by appealing to the ideological or religious terms of reference of the other. (So, for instance, in current conflicts between the modern West and certain strains of Islam, the West could find resources within the sacred literature of Islam itself to query the grounds of Islamic antagonism and enjoin Islamic good will.) Anthropocentric attitudes can be recruited to the cause of the environment via a demonstration that what sets humanity above and apart from the rest of life is our human capacity for awareness of metaphysical unity. In the very act of affirming our human superiority then, we are at the same time acknowledging our unity, our kinship, with all of Creation, and our consequent responsibility for it.

Faced with the devastating environmental and social impacts of corporate capitalism and contemporary global markets, the advocate of letting-be might search for the essence of capitalism and find it in the liberal tenet of freedom – the right of everyone to pursue their own good in their own way subject only to a minimal requirement that their doing so not extinguish the like right of others. She notices the isomorphism between this principle of freedom and her own principle of letting-be. Instead of opposing this freedom, out of disgust for the havoc it wreaks on the environment and on the fabric of society, she expands its scope: truly to follow through on liberalism, she points out, is to let *everything*, human and other-than-human alike, work out its own good in its own way – in other words, to let everything be. How is she to convince liberals that not only human beings but all things are entitled to work out their own good in their own way? She will have to persuade them to change their metaphysical premise. And how is she to accomplish this? By couching her argument within her opponents' terms of reference. If, as is generally the case, liberals' terms of reference are rationalist, then she must demonstrate rationally that a change of metaphysical premise is needed. She must out-reason, out-argue, the proponents of reason and argument.

The advocate of letting-be thus takes the world as she finds it – ecologically degraded, infested with ferals, rife with prejudicial attitudes, desecrated by commerce. She doesn't change the world. But by intelligently engaging with it as it is, rather than contradicting it, and by seeking synergistically to extend and enlarge the conativities she encounters there, she allows the world to change itself.

Synergy in this sense is, again, comparable to the Taoist notion of inaction, *wu wei*. Inaction, as was noted earlier, is not mere inactivity, but activity that is undertaken with rather than against the grain of conativity, whether this be the conativity of self or world. One who is committed to inaction in this sense seeks to overcome oppression, disturbance and malaise not by confronting them head on, in the name of utopian norms, but by attuning and joining herself to ambient conativites, to the conative dynamics of self increase. Although this synergistic modality can be articulated discursively – as it has been here – it can operate nondiscursively. It is called forth not by discursive deliberation but by encounter with the dynamics of a psychically activated world.

4. DISCOVERING THE TAO IN AUSTRALIA

The position that I have outlined in this paper is then basically a Taoist one. Nature, according to my definition, is more or less equivalent to the Tao: it is the wise way the world unfolds when left to its own devices. The Taoism of Lao Tzu does not announce itself as panpsychist, but clearly a world animated by the Tao is one which is possessed of some intelligent inner principle, a principle that can be trusted to guide us into the deepest channels of life.

It is not my place to comment in detail here on the affinities between the broadly Taoist attitude of letting be and certain fundamental characteristics of Aboriginal thought. Suffice it to say that Aboriginal cultures evince a powerful engagement with the given that ensures their continuity with their own past but also their flexibility in the face of an almost unimaginable scale of externally imposed change. For while not *craving* the possible and the ideal, they exhibit a genius for accommodating the new once it has become actual. One of the flashpoints in the evolution of my own thinking occurred when a non-indigenous friend who had married into an Aboriginal family in the far north-west of Australia told me about an elder there who included *motorboats* in his Dreaming stories. Years later I happened to find myself living for a while in the very community to which the old man – by now deceased – had belonged, and I was enchanted by the way in which the people in this community refused nothing. They accepted – though they never craved – anything and everything that drifted their way, all the trappings and junk of modern civilization. But in the process of accepting this tawdry stuff, they also uncannily Aboriginalized it, so that it assumed an entirely different significance in the context of their community from its intended significance within the framework of a capitalist culture. Somehow, through this affectionate trust in the given, the everyday was rendered numinously spiritual, and the spiritual unpretentiously everyday.

Mary Graham has declared that one of the most taken-for-granted assumptions of Aboriginal thought is that spirit is real; another is that land is all there is (Graham 1992). That is to say, spirit has a status, in Aboriginal thought, as incontestable as that of energy and matter; and, since there is no heaven and hell, and since theories and ideas, however dazzling, are not real, land is ultimately the only thing that exists. If 'land' is expanded to encompass the concrete given – all that is actual in a physical sense – then I think that the attitude of letting be follows from these twin premises: spirit animates the given rather than existing in the realm of the abstract, so we connect with spirit by engaging – and not unnecessarily interfering – with the given. By embracing the given even in its most adulterated forms, we reinhabit our own contemporary, mundane reality in the same kind of profound way that traditional Aboriginal peoples inhabited their reality, the still edenic land.

Aboriginal peoples learned to inhabit the real rather than escaping into the ideal by remaining attuned to the wisdom that this peaceful old land imparts to those who pay attention to it. I believe that my own early glimpses of this way of living came to me not in the first instance through explicit Aboriginal influences – though these influences later helped to bring it to consciousness – but through the opportunities for such attentiveness that were vouchsafed me as a child. Born into this intimately companionable land that has for so long been singing along, humming along, with its human inhabitants, non-Aboriginal Australians might also, if we collectively pause to feel the resonance of the endlessly poetic communiques that surround us, rediscover, in a contemporary context, some of the fundamental aspects of the Aboriginal relation to the world.

- Parts of this article originally appeared in "Letting the World Grow Old: an Ethos of Countermodernity", *Worldviews: Environment, Culture, Religion* vol 3 no 2, 1999, pp 119-137; The White Horse Press, Cumpidge, UK
- My argument for a broadly panpsychist view of matter was begun in my book, *The Ecological Self* (Mathews 1991) and developed further in *For Love of Matter: a Contemporary Panpsychism*, SUNY Press, Albany NY, 2003. The present article is extracted from a chapter of a further book, forthcoming in 2004, in which the implications of panpsychism for environmental praxis are drawn out.
- I have expanded elsewhere on the thesis that living systems, including individual organisms, may be characterized as self-realizing systems imbued with their own conatus. (Mathews 1991, 2003)
- To defend this essentialist claim against the social constructionism of contemporary postmodernism and poststructuralism would take me too far afield here. Suffice it to say that at a minimal level, this claim is self-evidently true: people's hunger, thirst, sociability, disposition to learn and use language, to build cultures, to live collectively, all operate independently of ideology – which is not to say that they may not become disturbed by ideology in dysfunctional circumstances.
- It could be said that it is part of the 'disposition' of things to be susceptible of manipulation by intentional agents, and to respond to such manipulation in determinate ways. While this is no doubt a fair semantical point, it overlooks the significance of the patterning that occurs when things are not subjected to manipulation compared with the failure of such patterning when they are subject to arbitrary human interventions.
- This is not to say that nature necessarily has an answer for everything. The scenario that immediately springs to mind is that of the life-shattering asteroid. It is not obvious that the biosphere has a 'contingency plan' for this circumstance. On the other hand, the likelihood of this catastrophe occurring is very small.
- I have observed a similar attitude to junk and rubbish in Aboriginal communities in Australia. Lots of litter and old machinery and cars and fridges and so on are left lying around in some of the remoter communities, apparently on the assumption that these things, like all others, have their place in the world, so there is no point in pretending that they do not exist by putting them out of sight. They will in time, again like everything else, be received back into the land, back into the cycles of life.
- For a comparable account of the way the land claims its native sons and daughters in the Aboriginal world, see Deborah Bird Rose 1992, 1996.
- Vandana Shiva offers a beautiful account of the incompatibility of the profit motive with ecology in Shiva, 1988.
- Anthony Giddens has explored the peakdown of the left-right distinction in the context of globalization, and has identified the conservative element of ecological politics. He regards ecological politics however as an essentially confused response to the new global situation of de-traditionalization and the humanization of nature, and no extension of it, such as is proposed here on the basis of a new metaphysical premise, holds any kind of key. The way forward in the new global context, according to Giddens, is via a multivalent approach that draws on both conservative and socialist thinking. See Giddens, 1994.
- Biologist Tim Low offers many examples of waste products that are, often inadvertently, recycled to the benefit of other-than-human species. In a study of the ecology of sewerage, for example, he details many ways in which wildlife thrives even on untreated waste. Albatrosses used to travel from as far afield as islands east of South America to fatten up on the abattoir wastes that were once pumped into the ocean through Sydney sewers. As many as 700 birds would congregate to

feed on the “plume of lard” that was discharged raw into the harbour. In the 1970s Sydney upgraded its sewerage treatment plants and the albatross population plummeted. The wandering albatross is now on the endangered list. See Low, 2002.

- While such commercial use of wildlife certainly illustrates the principle of synergy, I think any in-practice proposal to harvest wildlife must be subjected to rigorous scrutiny. Commercial harvesting holds many, many dangers for wildlife as it will rarely be undertaken on a genuinely synergistic basis or respect the social and age profile of a species; for this reason well-meaning ecological proposals can result in destruction and harm for wildlife.
- Neil Byron, a commissioner at the Productivity Commission of Australia, has said that in many parts of Australia, “ farmers are trying to produce bales of wool and bags of wheat, and not making a great deal of money out of it, and it may turn out to be much better for land and much better for the farm family to produce a few less bales of wool and bags of wheat and a bit more environmental services, whether that’s in water quality or yield, or wildlife conservation services, or any of this set of ecosystem services.”

Certainly! Aligning oneself with the world involves developing a holistic understanding of one's surroundings, cultivating empathy and compassion for others, and actively contributing to the well-being of the global community. Here are comprehensive steps to help you align yourself with the world:

1. Cultivate Awareness:

- **Self-Reflection:** Take time to introspect and understand your values, beliefs, and aspirations.
- **Stay Informed:** Keep abreast of current events, global issues, and diverse perspectives through reputable sources of information.

2. Develop Empathy and Understanding:

- **Practice Active Listening:** Listen attentively to others' experiences, perspectives, and concerns without judgment.
- **Seek Diversity:** Engage with people from different backgrounds, cultures, and viewpoints to broaden your understanding and empathy.

3. Foster Connection and Community:

- **Build Relationships:** Cultivate meaningful connections with family, friends, and communities to create a support network and sense of belonging.
- **Volunteer:** Contribute your time and skills to local or global initiatives that address social, environmental, or humanitarian challenges.

4. Promote Equity and Justice:

- **Advocate for Change:** Speak up against injustice, discrimination, and inequality in your community and beyond.
- **Support Marginalized Groups:** Stand in solidarity with marginalized communities and support efforts to amplify their voices and rights.

5. Practice Sustainability:

- **Reduce Consumption:** Minimize your environmental footprint by conserving resources, reducing waste, and adopting sustainable practices in daily life.
- **Promote Conservation:** Support initiatives and policies that protect biodiversity, preserve natural habitats, and mitigate climate change.

6. Embrace Cultural Exchange and Learning:

- **Embrace Diversity:** Celebrate cultural diversity and engage in cross-cultural exchange to foster mutual understanding and respect.
- **Educate Yourself:** Learn about different cultures, traditions, and histories to promote intercultural dialogue and appreciation.

7. Foster Personal Growth and Well-Being:

- **Prioritize Self-Care:** Take care of your physical, mental, and emotional well-being to sustain your capacity for positive impact and resilience.
- **Continuous Learning:** Pursue opportunities for personal and professional growth to expand your knowledge, skills, and perspectives.

8. Practice Gratitude and Mindfulness:

- **Gratitude Practice:** Cultivate gratitude for the blessings in your life and acknowledge the interconnectedness of all beings.
- **Mindful Living:** Practice mindfulness to stay present, reduce stress, and cultivate a deeper connection with yourself and the world around you.

9. Act with Integrity and Compassion:

- **Lead by Example:** Demonstrate integrity, honesty, and compassion in your interactions and decision-making.
- **Act Responsibly:** Take responsibility for your actions and their impact on others, striving to do no harm and contribute positively to the world.

10. Reflect and Adapt:

- **Regular Reflection:** Set aside time for reflection to evaluate your alignment with the world, identify areas for growth, and recalibrate your actions and priorities.
- **Stay Flexible:** Remain open to feedback, new information, and changing circumstances, adapting your approach as needed to better align with your values and the needs of the world.

By following these steps and continuously striving to align yourself with the world, you can contribute to a more compassionate, equitable, and sustainable global community. Aligning oneself with the way the world really works and the complexities of the world involves gaining a deep understanding of various systems, dynamics, and patterns that govern our reality. Here are comprehensive steps to help you align yourself with the complexities of the world:

1. Cultivate Curiosity and Open-mindedness:

- **Seek Knowledge:** Develop a thirst for learning and understanding the world around you through reading, research, and exploration.
- **Challenge Assumptions:** Question your existing beliefs and assumptions, remaining open to new perspectives and insights.

2. Study Systems Thinking:

- **Learn about Systems:** Explore the principles of systems thinking, understanding how different components interact to form complex systems.
- **Analyze Interconnections:** Identify interdependencies and feedback loops within systems to grasp their holistic nature.

3. Embrace Complexity:

- **Acknowledge Uncertainty:** Accept the inherent complexity and uncertainty of the world, recognizing that simple solutions may not always suffice.
- **Appreciate Emergence:** Understand how complex phenomena emerge from the interactions of simpler elements, often leading to unexpected outcomes.

4. Study Multidisciplinary Perspectives:

- **Explore Diverse Disciplines:** Study various fields such as economics, psychology, sociology, ecology, and geopolitics to gain diverse perspectives on complex issues.
- **Integrate Insights:** Seek to integrate insights from different disciplines to develop a more comprehensive understanding of complex phenomena.

5. Analyze Dynamic Systems:

- **Study Dynamic Systems:** Learn about dynamic systems such as ecosystems, economies, and social networks, understanding their non-linear behavior and feedback mechanisms.
- **Identify Patterns and Trends:** Analyze patterns and trends within dynamic systems to anticipate changes and potential future scenarios.

6. Develop Critical Thinking Skills:

- **Evaluate Evidence:** Practice critical thinking by evaluating evidence, assessing arguments, and discerning fact from opinion.
- **Recognize Biases:** Be aware of cognitive biases and logical fallacies that may distort your perception of reality.

7. Engage in Continuous Learning:

- **Stay Informed:** Keep abreast of current events, scientific discoveries, and emerging trends to stay informed about the ever-changing world.
- **Adapt and Evolve:** Remain flexible and adaptable, continuously updating your understanding and skills to navigate evolving complexities.

8. Apply Mental Models:

- **Choose Relevant Models:** Select appropriate mental models such as Occam's Razor, Second-Order Thinking, or Bayesian Reasoning to analyze and navigate complex situations.
- **Apply Models Thoughtfully:** Use mental models as frameworks for understanding and decision-making, recognizing their limitations and context-specific applicability.

9. Foster Collaboration and Dialogue:

- **Engage in Discourse:** Participate in discussions and dialogues with individuals from diverse backgrounds and viewpoints to broaden your perspective.
- **Seek Collaborative Solutions:** Work collaboratively with others to address complex challenges, leveraging collective intelligence and creativity.

10. Practice Adaptability and Resilience:

- **Adapt to Change:** Embrace change as a constant in the complex world, remaining flexible and resilient in the face of uncertainty.
- **Learn from Failure:** View setbacks and failures as opportunities for learning and growth, iterating and improving your approach over time.

11. Reflect and Iterate:

- **Regular Reflection:** Set aside time for reflection to assess your understanding of the complexities of the world, identify areas for growth, and refine your approach.
- **Iterative Learning:** Embrace a process of continuous improvement, iterating on your understanding and strategies based on feedback and experience.

By following these steps and actively engaging with the complexities of the world, you can develop a deeper understanding of reality and align yourself more effectively with its intricate dynamics and systems.

Understanding how the world really works and how the complex world operates involves grasping a multitude of interconnected systems, phenomena, and dynamics. Here are comprehensive steps to help you develop a deeper understanding:

Steps to Understand How the World Really Works:

1. Study Natural Sciences:

- **Physics, Chemistry, Biology:** Gain foundational knowledge of natural sciences to understand fundamental principles governing the physical world.
- **Ecology, Geology, Astronomy:** Explore ecological systems, geological processes, and celestial phenomena to understand Earth's interconnectedness with the cosmos.

2. Explore Social Sciences:

- **Economics:** Study economic systems, market dynamics, and resource allocation to understand societal behavior and decision-making.
- **Psychology, Sociology:** Explore human behavior, social interactions, and cultural influences to understand societal structures and dynamics.

3. Understand Political and Geopolitical Dynamics:

- **Political Science:** Study political systems, governance structures, and power dynamics at local, national, and global levels.
- **Geopolitics:** Explore the interactions between nations, geopolitical interests, and the impact of geography on international relations.

4. Analyze Technological Advancements:

- **Information Technology:** Understand the role of technology in shaping communication, commerce, and social interactions.
- **Emerging Technologies:** Explore advancements in fields like artificial intelligence, biotechnology, and renewable energy to anticipate future trends.

5. Consider Environmental and Ecological Factors:

- **Climate Science:** Study climate patterns, environmental degradation, and the impact of human activities on ecosystems.
- **Biodiversity and Conservation:** Understand the importance of biodiversity and conservation efforts in maintaining ecological balance.

Steps to Understand How the Complex World Really Works:

1. Study Systems Thinking:

- **Systems Theory:** Learn about systems thinking and complexity science to analyze interconnected systems and emergent properties.
- **Feedback Loops:** Understand how feedback loops and nonlinear dynamics contribute to complex behavior in systems.

2. Analyze Networks and Interconnections:

- **Social Networks:** Explore the structure and dynamics of social networks, understanding how information and influence flow within them.
- **Supply Chains:** Analyze global supply chains and logistical networks to understand the interdependence of economies and industries.

3. Consider Multidimensional Perspectives:

- **Multidisciplinary Approach:** Integrate insights from diverse fields to analyze complex phenomena from multiple perspectives.
- **Interdisciplinary Collaboration:** Engage in interdisciplinary collaboration to address complex challenges and develop holistic solutions.

4. Evaluate Emergent Properties:

- **Emergence:** Understand how complex systems exhibit emergent properties that cannot be fully explained by analyzing their individual components.
- **Self-Organization:** Explore self-organizing principles in complex systems, such as flocking behavior in birds or traffic flow in cities.

5. Recognize Nonlinear Dynamics:

- **Chaos Theory:** Study chaos theory to understand the behavior of nonlinear systems and the concept of sensitive dependence on initial conditions.
- **Tipping Points:** Analyze tipping points and phase transitions in complex systems, understanding how small changes can lead to significant shifts.

Steps to Synthesize Understanding:

1. Integration of Knowledge:

- **Synthesize Insights:** Integrate knowledge from various disciplines to develop a comprehensive understanding of how the world operates.
- **Identify Patterns:** Recognize recurring patterns and universal principles that apply across different domains.

2. Critical Thinking and Analysis:

- **Evaluate Evidence:** Practice critical thinking to evaluate evidence, arguments, and hypotheses related to complex phenomena.
- **Analyze Cause and Effect:** Investigate causal relationships and unintended consequences in complex systems.

3. Continuous Learning and Adaptation:

- **Stay Informed:** Keep abreast of new developments and emerging trends through continuous learning and exploration.

- **Adaptability:** Remain flexible and adaptable in your understanding, updating your mental models and frameworks as new information becomes available.

4. Engage in Dialogue and Collaboration:

- **Exchange Perspectives:** Engage in dialogue with others to exchange perspectives, share insights, and deepen understanding.
- **Collaborative Problem-Solving:** Work collaboratively with diverse stakeholders to address complex challenges and explore innovative solutions.

5. Reflect and Iterate:

- **Regular Reflection:** Set aside time for reflection to consolidate your learning, identify areas for further exploration, and refine your understanding.
- **Iterative Approach:** Embrace an iterative approach to learning, revisiting concepts and frameworks to deepen your understanding over time.

By following these comprehensive steps, you can develop a nuanced understanding of how the world really works and how the complexities of our interconnected world manifest across various domains. This understanding will enable you to navigate and engage with the world more effectively, whether it be in personal, professional, or societal contexts.

Aligning oneself with the complexities of the world involves developing a deep understanding of interconnected systems, embracing adaptability, and cultivating a holistic perspective. Here's how you can align yourself with the complex world:

1. Cultivate Systems Thinking:

- **Understand Interconnections:** Recognize that the world is composed of interconnected systems, where changes in one area can have ripple effects elsewhere.
- **Analyze Feedback Loops:** Identify feedback loops and nonlinear dynamics within systems to understand how they evolve over time.

2. Embrace Complexity:

- **Accept Uncertainty:** Embrace the inherent uncertainty and unpredictability of complex systems, understanding that outcomes may be influenced by multiple factors.
- **Appreciate Emergence:** Recognize that complex phenomena often emerge from simple rules and interactions, leading to unpredictable outcomes.

3. Foster Adaptability:

- **Remain Flexible:** Be open to change and adapt your mindset and strategies in response to evolving circumstances.
- **Learn from Feedback:** Embrace feedback as an opportunity for growth, adjusting your approach based on lessons learned from successes and failures.

4. Develop Multidisciplinary Perspectives:

- **Explore Diverse Disciplines:** Engage with knowledge and insights from various fields, integrating perspectives from science, humanities, arts, and social sciences.
- **Synthesize Insights:** Synthesize diverse perspectives to develop a comprehensive understanding of complex issues and phenomena.

5. Promote Collaboration and Dialogue:

- **Seek Collaboration:** Collaborate with individuals from diverse backgrounds and expertise to tackle complex challenges collectively.
- **Facilitate Dialogue:** Foster open and constructive dialogue to exchange ideas, share insights, and explore innovative solutions.

6. Practice Critical Thinking:

- **Evaluate Information:** Critically evaluate information and sources, discerning fact from opinion and identifying biases and assumptions.
- **Analyze Cause and Effect:** Analyze causal relationships and unintended consequences in complex systems to anticipate potential outcomes.

7. Act Responsibly and Ethically:

- **Consider Long-Term Impacts:** Assess the long-term consequences of your actions on both human and environmental systems.
- **Promote Equity and Justice:** Advocate for fairness, equity, and social justice in your interactions and decision-making.

8. Cultivate Resilience:

- **Build Resilience:** Develop resilience to navigate uncertainty and adversity, bouncing back from setbacks and challenges.
- **Maintain Balance:** Strike a balance between adaptation and stability, recognizing the importance of both continuity and change.

9. Engage in Continuous Learning:

- **Stay Curious:** Foster a lifelong commitment to learning and exploration, staying curious about the world and its complexities.
- **Keep Abreast of Developments:** Stay informed about emerging trends, scientific discoveries, and global events to adapt to evolving circumstances.

10. Foster Empathy and Compassion:

- **Practice Empathy:** Cultivate empathy for others by seeking to understand their perspectives, experiences, and challenges.
- **Act with Compassion:** Act with compassion and kindness towards others, recognizing our interconnectedness and shared humanity.

11. Reflect and Iterate:

- **Regular Reflection:** Set aside time for introspection and reflection to assess your alignment with the complex world, identify areas for growth, and refine your approach.
- **Iterative Improvement:** Embrace an iterative approach to personal and professional development, continuously refining your understanding and strategies over time.

By embracing these principles and practices, you can align yourself with the complexities of the world, navigate uncertainty with resilience, and contribute positively to the collective well-being of humanity and the planet.

Understanding how the world really works and how the complex world operates requires a multifaceted approach that considers various disciplines, systems, and dynamics. Here's an overview of both concepts:

How the World Really Works:

1. Fundamental Principles:

- **Natural Laws:** The world operates based on fundamental laws of physics, chemistry, and biology, governing the behavior of matter and energy.
- **Economic Principles:** Economic systems function based on principles of supply and demand, competition, and resource allocation.
- **Social Dynamics:** Human societies are shaped by cultural norms, social structures, and interpersonal relationships.

2. Interconnected Systems:

- **Ecological Systems:** Ecosystems are interconnected networks of living organisms and their environment, where changes in one component can affect the entire system.
- **Economic Systems:** Global economies are interconnected through trade, finance, and supply chains, influencing each other's stability and growth.
- **Political Systems:** Political institutions and governance structures shape the distribution of power, influence, and decision-making within societies and across nations.

3. Emergent Phenomena:

- **Emergence:** Complex phenomena emerge from interactions among simpler components, leading to properties and behaviors that cannot be predicted from individual parts.
- **Self-Organization:** Systems exhibit self-organizing properties where order and patterns emerge spontaneously from local interactions, without centralized control.

How the Complex World Really Works:

1. Complex Adaptive Systems:

- **Nonlinear Dynamics:** Complex systems exhibit nonlinear behaviors, where small changes can lead to disproportionate effects or sudden shifts in behavior.
- **Feedback Loops:** Feedback mechanisms within systems can amplify or dampen effects, leading to self-regulation or instability.

2. **Multidimensional Interactions:**

- **Network Effects:** Interconnected networks, such as social networks or ecological webs, generate complex interactions and feedback loops that shape their structure and dynamics.
- **Interdisciplinary Perspectives:** Complex problems often require interdisciplinary approaches that integrate insights from multiple fields to address their multifaceted nature.

3. **Uncertainty and Adaptation:**

- **Uncertainty:** Complex systems are inherently uncertain, with multiple interacting variables and dynamic changes over time.
- **Adaptive Behavior:** Agents within complex systems exhibit adaptive behavior, adjusting their strategies and responses based on feedback and changing conditions.

4. **Emergent Properties and Patterns:**

- **Emergent Properties:** Complex systems exhibit emergent properties that arise from interactions among their components, such as collective behaviors or spontaneous order.
- **Pattern Formation:** Patterns and structures emerge within complex systems, often reflecting underlying principles of self-organization and emergent phenomena.

5. **Dynamics of Change:**

- **Resilience and Adaptability:** Complex systems display resilience, the ability to absorb disturbances and maintain stability, as well as adaptability, the capacity to evolve and respond to changing conditions.
- **Phase Transitions and Tipping Points:** Complex systems can undergo phase transitions or reach tipping points, leading to abrupt changes in behavior or state.

Understanding how the world really works and how the complex world operates requires a nuanced understanding of fundamental principles, interconnected systems, emergent phenomena, and adaptive dynamics. By embracing complexity and adopting interdisciplinary perspectives, we can better navigate the intricacies of our ever-changing world.

Step - Letting The World Do The Work

For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

PART 12: Deep Work and Decision Making

Step 78-Slow Down

- 1. Do Not Rush Any Tasks I will do At Any Time.**
- 2. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”**
- 3. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.**

- I. We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- II. The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- III. But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- IV. Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- V. We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- VI. As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always seems that the time-train is

pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

VII. Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.

VIII. When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.

IX. The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom — the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one

French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- X. Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don't go away never to be seen again. It's not like we make a bad decision and we're done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we're doing more.

4. Do The Tasks Slowly, and Step By Step.

5. The Art of Slowing down and Do Not Rush Anything.

- I. The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we're going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- II. Too many of us see going nowhere as turning away from something rather than turning towards something.
- III. Going nowhere isn't about turning your back on the world; it's about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- IV. The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it's how we respond to our experiences, not the experiences themselves, which shape us.
- V. The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- VI. “Our creations come not when we're out in the world, gathering impressions, but when we're sitting still, turning those impressions into sentences.

Step 79-NOT MULTITASK.

1. Of course you can do more than one thing at once. The catch is you can't do more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time. When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.
2. There is a mental cost—called a switching cost—to all of this multitasking. But that's not all it makes deep thinking impossible.
3. I think people that multitask pay a huge price. They think they're being extra productive, and I think they're (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don't have time to think about anything deeply. You're giving the world an advantage you shouldn't do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can't succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
4. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: "You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube."
5. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don't do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.
6. Listen and Apply The Following Books:

A. The Multitasking Mind By Dario Saliveci

Step 80-You Have Required To Do The Work For Decision Making.

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XIII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIV. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very very hard to have an opinion about anything.

XV.Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XVI.Never use cheap shots to win argument, like logical fallacies.

XVII.Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.

II. First Left Hand Column Are My Arguments.

III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.

IV. Third Left Column are My Responses to the Opponent responses.

V. Fourth Left Hand Column are My Rebuttal.

VI. Fifth Left Hand Column are Opponent Rebuttal.

VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.

VIII. Seventh Left Hand Column is the Final My Rebuttal.

IX. Eight Left Hand Column is The opponent Rebuttal.

X. Ninth Left Hand Column is my closing statements.

XI. Tenth Left Hand Column is the opponent closing statements.

XII. Eleventh Left Hand Column is the Cross Examination.

- My Answer.

- Opponent Answer.

- My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 81-Use Rules of Reading for Decision Making

1. Listen, Follow and Apply Rules of Reading of Bible Study, Deep Work, Deep Study, Analysis, Syntopicon and Research For Decision Making.
 - A. **VERY VERY FAST Reading- Skimming. Pages 47-51.**
 - B. **VERY FAST READING- Entertainment.**
 - I. **Method 1-Speed Reading. FAST Reading. Pages 59-64.**
 - C. **FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.**
 - I. **Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**
 - II. **Method 2-Use 80/20 Principle For Reading. Pages 68.**
 - III. **Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.**
 - IV. **Method 4-Flip Through Pages and Analyse. Page 70.**
 - V. **Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.**
 - VI. **Method 6-Devotional Bible Read. Pages 73-74.**
 - D. **Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.**
 - I. **Method 1-Chapter Summary Method. Pages 143-147.**
 - II. **Method 2-Character Quality Method. Pages 148-160.**
 - III. **Method 3-Thematic Method. Pages 161-163.**
 - IV. **Method 4-Biographical Method. Pages 164-176.**
 - V. **Method 5-Topical Method. Pages 177-180.**
 - VI. **Method 6-Word Study Method. Pages 181-189.**
 - VII. **Method 7-Book Background Method. Pages 190-194.**
 - VIII. **Method 8-Book Survey Method. Pages 195-205.**

- IX. Method 9-Chapter Analysis Method. Pages 206-215.**
- X. Method 10-Paragraph Study. Pages 216-229.**
- XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- XII. Method 12-Book Synthesis Method. Pages 235-238.**
- XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- XIV. Method 14-Studying Bible Prophecy. Pages 246-259.**
- XV. Method 15-Typological Study Method. Pages 260-262.**
- XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- XVII. Method 17-Inductive Bible Study Method. Pages 269-296.**
- XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

E. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

2. Apply The Books To My Decision

Step 82 - Decision Making Books

1. **Listen, Follow And Apply Rules of Reading Part 1 to 10, before looking into Decision Making.**
2. **Listen, Follow and Apply the following Books.**
 - A. **Critical Thinking_ Tools for Taking Charge of Your Professional and Personal Life.**
 - B. **Decisive_ How to Make Better Choices in Life and Work.**
 - C. **The Decision Book_ Fifty Models for Strategic Thinking.**
 - D. **The Thinking Manager's Toolbox_ Effective Processes for Problem Solving and Decision Making.**
 - E. **Thinking_ The New Science of Decision-Making, Problem-Solving, and Prediction.**
 - F. **How To Read A Book.**
 - G. **Socratic Method.**

Step 83-Decision Making

Decision Making Tools

Getting the World to Do the Work for You

“What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson.” Joseph Tussman.

The key to getting what you want out of life is to identify how the world works and align yourself accordingly. The problem is we often think the world *should* work differently than it does. The word “should” is important. Because we think the world should work in a way that it doesn’t, our approach is suboptimal.

Why don’t we align ourselves with reality?

Part of the answer is we don’t listen to the feedback of reality. When we don’t get the outcome we’re seeking, the last place we look is with our actions. It’s too easy to wiggle out of responsibility by blaming others and circumstances. It’s not that this approach is entirely ineffective. We eventually get the job half done in twice the time. The person working with the world, however, gets the job fully done in half the time.

The most common source of feedback is people not reality. One problem with feedback from people is that it’s hard to give someone else high quality feedback. Think about it. People will tell you a few helpful things but they’ll often avoid the big thing that’s holding you back. They don’t want to hurt your feelings. They want you to like them. That’s not the biggest problem. The biggest problem is that people rarely know much more than you do. If they had all the answers, they’d get better results.

Another form of people feedback comes from groups, institutions, and society. This is the way things have been done. And while there might be good reason for doing things the same way they’ve always been done, if you take your feedback from these folks, you’ll incrementally improve what’s already exists rather than use first principles to design something new. If existing institutions knew what they were doing, we wouldn’t have startups or bankruptcy lawyers.

How do we identify how the world really works?

Outcome over ego. You are accountable for your outcomes. When you take responsibility for your outcomes you get feedback from reality. When you get feedback from reality, you adjust your behavior.

The Four Villains of Decision Making

1. **Narrow Framing:** "... the tendency to define our choices too narrowly, to see them in binary terms. We ask, "Should I break up with my partner or not?" instead of "What are the ways I could make this relationship better?"
2. **Confirmation Bias:** "When people have the opportunity to collect information from the world, they are more likely to select information that supports their preexisting attitudes, beliefs, and actions." We pretend we want the truth, yet all we really want is reassurance.
3. **Short-term Emotion:** "When we've got a difficult decision to make, our feelings churn. We replay the same arguments in our head. We agonize about our circumstances. We change our minds from day to day. If our decision was represented on a spreadsheet, none of the numbers would be changing—there's no new information being added—but it doesn't feel that way in our heads."
4. **Overconfidence:** "People think they know more than they do about how the future will unfold."

Why We Fail At Effective Decision Making

1. We're unintentionally stupid. I like to think that I'm rational and capable of interpreting all information in a non-biased way but that's a dream. Cognitive biases are great at explaining how our evolutionary programming leads us astray. Knowledge of these biases in advance rarely helps us make better decisions. There are, however, many easily recognizable situations that increase the odds we're about to do something stupid. Whether we're tired, overly focused on a goal, rushing, distracted, operating in a group, or under the influence of a group, we're more prone to stupidity.²

2. We have the wrong information. Making decisions with the wrong assumptions or facts is likely to lead to disaster.

3. We use the wrong model. We use mental models to make decisions. The quality of those models determines the quality of our thinking. There are a variety of reasons that we use false, incomplete, or incorrect models. Novices are prone to using models that the expert knows are incomplete or irrelevant. The odds of employing the wrong models increase as the pace of environmental change increases.

4. We fail to learn. We all know the person that has 20 years of experience but it's really the same year over and over. Well, that person is sometimes us. If we don't understand how we learn, we're likely to make the same mistakes over and over.

5. Looking over doing good. Our evolutionary programming conditions us to do what's easy over what's right. After all it's often easier to signal being virtuous than actually being virtuous. We unconsciously make choices based on optics, politics, and defendability. We hate criticism and seek the validation of our peers and superiors. We often want to feel good about ourselves first and have the outcome we desire second.

How We Make Decisions

When was the last time you thought about how you make decisions?

If you're like most people, you've never been explicitly taught how to make effective decisions. You make decisions like a golfer who never took any lessons: miserable with the state of your game and yet not seeking to learn a better swing, and instead hoping for the best every time you lift the club. Hoping that this time your choice will finally work out.

In the early 1980s, Charlie Munger and his partner Warren Buffett realized that a Savings & Loan operation they owned, as with the rest of the industry, was doomed to fail miserably due to forces outside of their control. At a time when almost none of their peers were taking action, they changed course dramatically, massively reducing the effect of the bank's failure on the rest of their business holdings. These two men knew they had to act much differently than their peers.

It worked: The S&L industry collapsed, yet Munger and Buffett escaped with barely a scratch. They saved themselves a great deal of stress and financial pain by applying a uniquely effective system of organized common sense. In hindsight, it seems like an obvious good decision; at the time, it seemed odd and unusual.

The lesson for us is that the people making consistently good decisions take advantage of how the world works. That's wisdom.

Real knowledge of the art of decision making, which remains true across time and circumstances, eras and epochs, can help increase the odds that we get what we want and reduce costly mistakes.

While everyone else is guessing, falling into old patterns, blindly following cognitive biases, we can be clear-headed and laser-focused.

That's what Farnam Street is all about.

Here are some examples of applying — or failing to apply — knowledge about how the world really works.

- It doesn't matter how smart you are if you don't realize where things are additive and where they are multiplicative. Nikola Tesla failed to understand Multiplication by Zero when he failed to realize that poor relations with others affected his life. While the Serbian-American was a brilliant inventor, he had difficulty relating to others, which made him difficult to work with. This problem cost him a Nobel Prize and a fortune that today would likely have made him the richest man in the world.
- While we all rely on maps, which are reductions of complexity, to make decisions, they are not always accurate. General George S. Patton Jr. understood that the map is not the territory. When he visited the troops near Coutances, he found them

sitting on the side of the road, studying a map. Responding to Patton's inquiry as to why they had not crossed the Seine, the troops informed him that they were studying the map and could not find a safe place to wade across. Patton informed them that he had just waded across it and it was not more than two feet deep.

- While we all like to be in the sexy industries, that desire shows an under-appreciation for the laws of thermodynamics. Smart companies like Berkshire Hathaway, guided by legendary investor Warren Buffett, understand that contrast is important. Sexy internet businesses are rarely effective, no matter how good they are, because the others are nearly just as good. What you want is contrast — to be the big fish in a small pond. And when you analyze the types of investments he's made over the years, that's what you find. If you're going to compete with people, you want to compete with people who are way less sophisticated than you.
- Understanding and applying the mental model of relativity helped Michael Abrashoff take the worst-performing ship in the US Pacific Fleet and turn it into the best. In his book, *It's Your Ship*, he wrote: "The most important skill a skipper can have is the ability to see through the eyes of the crew."

Questions to Ask

Decision-Making Checklist

- Is this an example of survivorship bias?
- Am I confusing the factor for selection with the result?
- Am I seeing a pattern where there isn't one?
- Am I changing my behaviour or opinion because others are doing/acting/thinking this way? Because of social proof?
- Am I looking at only the future costs and benefits? Disregard any costs to date.
- Do I feel obligated to return a favour here? Have they done something for me that might make me subject to reciprocity?
- Can I find disconfirming evidence for my current hypothesis? What are the limitations of this evidence? How might someone with the opposing viewpoint interpret this evidence?
- Is some sort of authority figure exerting an influence on me?
- What am I judging this in relation to? How would this look in a different context, compared to something else? What sort of small, gradual changes might I be missing?
- Am I overvaluing evidence because of my own experience or the ease with which I can recall it? Who can I get an opinion from who has a different expertise and experience than me?
- What evidence would I have to see to make a judgement about whether this situation is improving? What are clear and verifiable milestones?
- Am I trying to shape this into a story? What is my confidence level that I actually understand this?
- What predictions am I making about this? How confident am I? What historical decisions do I have recorded that might indicate my prediction level?
- What is the pessimistic scenario here? How far off is my own prediction from this scenario?
- Does this person (or do I) truly understand this situation? Or is it outside my circle of competence?
- What specific things can I actually control in this situation?
- What incentives are at play here? How do they likely affect the behaviour of those involved?
- Could this situation be explained by random variation, or regression to the mean?

- Was the process behind this good or bad, regardless of the result? Do I have enough evidence to evaluate the effectiveness of the process? What information did I have at the time?
- How can I reduce the number of choices here? What are the key factors I want to evaluate?
- Do I like this person? Is that affecting my decision-making process?
- Am I valuing this too highly because it is already mine? What does the market think?
- How unlikely is this event? Could it be caused by random chance?
- What is the devil's advocate view of this situation? Have we expressed our opinions independently?
- What is the rational response based on the probability and consequences of this event? What is the expected value or risk?
- Have I assessed this option based solely on costs and benefits? How would I evaluate it if it were available in abundance?
- What is the base rate in this situation? Is there an analogous situation I can rely on?
- What factors are independent and which are dependent in this situation?
- What anchors might I be using here when I shouldn't be?
- What are the objective upsides and downsides here? Am I overweighting the downside, or the fear of loss?
- Are we behaving differently here because we are a group? How are we evaluating individual performance?
- Is there an exponential factor at play here? Or is it linear?
- Am I competing with someone here? Is that changing my behaviour? What is my "line in the sand" if I'm bidding for something? Can I avoid an auction situation?
- What are the broader factors influencing the situation here? What degree of influence do they really have?
- Is there actually a link between these two factors? How do we know that one causes the other? How do we know they are linked at all?
- What are the limits of this piece of information? Is it causing me to look at other things favourably or unfavourably?
- If I try and evaluate from an outside view, what are all the possible outcomes for this situation? What are the associated risks with each path?
- What incentives is this person subject to? Is there a downside if the prediction is wrong? How good is his success rate?

- Am I dealing with a subset here? Am I trying to fit a plausible story to the situation?
- What if I present this situation in the opposite way? How does that change my perception?
- Am I just trying to act here? What if I just wait? Will I be able to better assess my options?
- Am I avoiding a particular path because the consequences are bad, but less bad than inaction?
- What bluntly honest friends, or enemies, could I ask for an honest assessment of strengths and weaknesses?
- Will this lead to long-term or short-term happiness? Would this lead to something guaranteed to be negative?
- How does this sample affect the conclusions I'm trying to make? What would be the ideal sample?
- Am I transferring qualities between things that are unrelated? Am I shooting the messenger?
- Is the sample size enough to make a conclusion about luck vs. skill here? Are there a large number of players here? (Likely to cause random winners). Can I disprove my conclusion?
- Am I trying to reinterpret things to maintain a previous attitude or belief?
- Am I making an impulsive decision right now? Am I playing the long game or short game?
- Is the reasoning behind this sound, or am I just going along with a "because" reason?
- Am I making this decision fresh? Am I well-rested and well-fed?
- Do I have a connection to this in some way?
- Does the average mean anything in this situation? What is the actual underlying distribution?
- Are financial incentives crowding my judgement? Are they crowding other incentives for the people involved here?
- What is being said here? Is it actually useful?
- How are these factors grouped? How has it changed? Have the groups been rearranged to manipulate the averages?
- What information is actually useful here? Am I falsely increasing my confidence levels because of additional, but useless information?

- Am I overvaluing parts of this because I put effort into them? What is the value of the result, discounting the process and effort put in?
- Is this sample size sufficient to draw conclusions? Or am I in fact extrapolating too far from a small sample?
- What expectations am I holding about this situation? Are they appropriate? What is the worst-case scenario?
- Am I evaluating this situation rationally? Or using intuition?
- Could this information apply to anyone? Are there any negatives, or are they all positive traits?
- Is this the best use of my time?
- Are my feelings about this subject, topic, or my current feelings contributing to my evaluation?
- Am I being critical with myself? How would I regard these internal observations if they were coming from someone else?
- Am I just trying to keep options open? What should I focus on *not* pursuing?
- Am I overvaluing this option because of the novelty?
- What is the source of this argument or opinion?
- What is the next best alternative to this option?
- Am I avoiding an option out of fear or jealousy of someone or something outdoing me?
- Am I overvaluing this information because it was the first I'd heard? Or because I heard it more recently?
- Am I overvaluing my own ideas? Who can give me an objective opinion?
- Have I put us in a position to guard against negative Black Swans? And take advantage of positive Black Swans?
- Am I within my circle of competence? Or am I trying to transfer knowledge from one domain to another?
- How do other people feel? What are their opinions? Have I truly gathered information about them?
- Do I know for sure this happened, or am I relying on memory?
- What groups are currently affecting my thinking? Have I sought opinions from outside my group?
- Am I falsely relying on probabilities just to avoid ambiguity?
- Would I make this same decision from a different position, if the status quo was different?

- Am I avoiding a decision out of fear of regret?
- Am I attributing undue weight to this factor because of its prominence? Which discreet factors am I failing to value?
- Is my behaviour different because I won this money or got something for free?
- Am I avoiding this because it's unpleasant? Can I set a deadline to force myself to get this done? Can I make a public commitment?
- Am I envious of something here?
- What are the facts and statistical distribution behind this story? Is the human aspect causing bias?
- Am I focusing on something here? What am I missing? What other scenarios are possible?
- What is the past performance behind this claim? Are there other situations similar to this where I can find data? What safeguards do I have in place?
- Is this a complex situation, or could I rely some on my emotions?
- What similar projects can I look at for objective data on my situation? What does the pre-mortem look like here?
- Have I gathered a number of sufficiently different perspectives to see how experts with different tools would solve this?
- Have I gone into enough detail in the plan on how to deal with this situation?
- Is there an illusion of skill here? Is this likely due to chance, or is there a demonstrated record of success?
- What features or factors am I missing here? Why do these factors exist instead of nothing?
- What has been cherry-picked here? Where are the negative results?
- Am I falsely attributing this to a single cause?
- What test subjects or information has been removed from the sample?
- Is this valuable information or just news?

List of Decision Making Tools

1. Overcome these villains and make better choices.

- You encounter a choice. But narrow framing makes you miss options. So **Widen Your Options**. How can you expand your set of choices?
- You analyze your options. But the confirmation bias leads you to gather self-serving information. So, **Reality-Test Your Assumptions**. How can you get outside your head and collect information you can trust?
- You make a choice. But short-term emotion will often tempt you to make the wrong one. So **Attain Distance Before Deciding**. How can you overcome short-term emotion and conflicted feelings to make better choices?
- Then you live with it. But you'll often be overconfident about how the future will unfold. So **Prepare to Be Wrong**. How can we plan for an uncertain future so that we give our decisions the best chance to succeed?

2. Inversion

Inversion is a powerful tool to improve your thinking because it helps you identify and remove obstacles to success. The root of inversion is “invert,” which means to upend or turn upside down. As a thinking tool it means approaching a situation from the opposite end of the natural starting point. Most of us tend to think one way about a problem: forward. Inversion allows us to flip the problem around and think backward. Sometimes it's good to start at the beginning, but it can be more useful to start at the end.

Spending time thinking about the opposite of what you want doesn't come naturally to most people. And yet many of the smartest people in history, have done this naturally.

Inversion helps improve understanding of the problem. By forcing you to do the work necessary to have an opinion you're forced to consider different perspectives.

3. Second Order Thinking

Almost everyone can anticipate the immediate results of their actions. This type of first-order thinking is easy and safe but it's also a way to ensure you get the same results that everyone else gets. Second-order thinking is thinking farther ahead and thinking holistically. It requires us to not only consider our actions and their immediate consequences, but the subsequent effects of those actions as well. Failing to consider the second and third order effects can unleash disaster.

Second-order thinking is more deliberate. It is thinking in terms of interactions and time, understanding that despite our intentions our interventions often cause harm. Second order thinkers ask themselves the question "And then what?" This means thinking about the consequences of repeatedly eating a chocolate bar when you are hungry and using that to inform your decision. If you do this you're more likely to eat something healthy.

First-level thinking looks similar. Everyone reaches the same conclusions. This is where things get interesting. The road to out-thinking people can't come from first-order thinking. It must come from second-order thinking. Extraordinary performance comes from seeing things that other people can't see.

Improving Your Ability To Think.

Here are three ways you can use to put second order thinking into practice today.

1. Always ask yourself "And then what?"
2. Think through time — What do the consequences look like in 10 minutes? 10 months? 10 Years? 1.
3. Create templates like the second image above with 1st, 2nd, and 3rd order consequences. Identify your decision and think through and write down the consequences. If you review these regularly you'll be able to help calibrate your thinking.
4. (Bonus) If you're using this to think about business decisions, ask yourself how important parts of the ecosystem are likely to respond. How will employees deal with this? What will my competitors likely do? What about my suppliers? What about the regulators? Often the answer will be little to no impact, but you want to understand the immediate and second-order consequences before you make the decision.

A lot of extraordinary things in life are the result of things that are first-order negative, second order positive. So just because things look like they have no immediate payoff, doesn't mean that's the case. All it means is that you'll have less competition if the second

and third order consequences are positive because everyone who thinks at the first order won't think things through.

Second-order thinking takes a lot of work. It's not easy to think in terms of systems, interactions, and time. However, doing so is a smart way to separate yourself from the masses.

4. The map is not the Territory

The map of reality is not reality. Even the best maps are imperfect. That's because they are reductions of what they represent. If a map were to represent the territory with perfect fidelity, it would no longer be a reduction and thus would no longer be useful to us. A map can also be a snapshot of a point in time, representing something that no longer exists. This is important to keep in mind as we think through problems and make better decisions.

5. How Not to Be Stupid-stupidity as overlooking or dismissing conspicuously crucial information.

6. Apply Rational Decision Process

1. Define the problem. Accurate judgment is required to identify and define the problem. Managers often err by (a) defining the problem in terms of a proposed solution, (b) missing a bigger problem, or (c) diagnosing the problem in terms of its symptoms. Your goal should be to solve the problem not just eliminate its temporary symptoms.

2. Identify the criteria. Most decisions require you to accomplish more than one objective. When buying a car, you may want to maximize fuel economy, minimize cost, maximize comfort, and so on. The rational decision maker will identify all relevant criteria in the decision-making process.

3. Weight the criteria. Different criteria will vary in importance to a decision maker. Rational decision makers will know the relative value they place on each of the criteria identified. The value may be specified in dollars, points, or whatever scoring system makes sense.

4. Generate alternatives. The fourth step in the decision-making process requires identification of possible courses of action. Decision makers often spend an inappropriate amount of search time seeking alternatives, thus creating a barrier to effective decision making. An optimal search continues only until the cost of the search outweighs the value of added information.

5. Rate each alternative on each criterion. How well will each of the alternative solutions achieve each of the defined criteria? This is often the most difficult stage of the decision-making process, as it typically requires us to forecast future events. The rational decision maker carefully assesses the potential consequences on each of the identified criteria of selecting each of the alternative solutions.

6. Compute the optimal decision. Ideally, after all of the first five steps have been completed, the process of computing the optimal decision consists of (a) multiplying the ratings in step 5 by the weight of each criterion, (b) adding up the weighted ratings across all of the criteria for each alternative, and (c) choosing the solution with the highest sum of weighted ratings.

7. Hamond and Raiffa 8 steps of decision

- 1. Work on the right problem.***
- 2. Identify all criteria.***
- 3. Create imaginative alternatives.***
- 4. Understand the consequences.***
- 5. Grapple with your tradeoffs.***
- 6. Clarify your uncertainties.***
- 7. Think hard about your risk tolerance.***
- 8. Consider linked decisions.***

8. Decision Journal Template

Whenever you're making a consequential decision, either individually or as part of a group, you take a moment and write down:

1. The situation or context.
2. The problem statement or frame.
3. The variables that govern the situation.
4. The complications or complexity as you see it.
5. Alternatives that were seriously considered and why they were not chosen (think: the work required to have an opinion).
6. A paragraph explaining the range of outcomes.
7. A paragraph explaining what you expect to happen and the reasoning and actual probabilities you assign to each projected outcome (The degree of confidence matters, a lot.)
8. The time of day you're making the decision and how you feel physically and mentally (If you're tired, for example, write it down.)

You have to make this part your own. I've seen others include:

- What's the primary thesis.
- What is the expected outcome(s).
- What are the second and third-order consequences.
- What is the worst-case scenario and why that's ok.
- What is the potential upside beyond the core thesis.
- What emotions am I experiencing.
- What is the opportunity cost (by doing this what am I not doing).
- What unique advantages or insights do I have in this situation.
- Who is the best person to make this decision.
- What does this look like in 5 weeks, 5 months, 5 years?

9. Charles Munger Two Steps

A simple and easy approach to decision making that prevents us from being manipulated.

1. Understand the forces at play.
2. Understand how your subconscious might be leading you astray.

While most of us make decisions daily, few of us have a useful framework for thinking that protects us when making decisions.

We're going to explore Munger's two-step process for making effective decisions and reducing human misjudgment.

In A Lesson on Elementary Worldly Wisdom, Charlie Munger offers a simple two-step filter for making effective decisions:

Personally, I've gotten so that I now use a kind of two-track analysis. First, what are the factors that really govern the interests involved, rationally considered? And second, what are the subconscious influences where the brain at a subconscious level is automatically doing these things-which by and large are useful, but which often malfunction.

One approach is rationality-the way you'd work out a bridge problem: by evaluating the real interests, the real probabilities and so forth. And the other is to evaluate the psychological factors that cause subconscious conclusions-many of which are wrong.

Let's take a closer look.

1. The Forces at Play

The key to the first step is knowing what you know and what you don't know. You need to understand your circle of competence. It's just as important to know what you don't know as it is to know what you know.

If you know what you don't know, you might still have to make a decision, but your approaches for making that decision will change. For example, if you're forced to make a decision in an area that you know is well outside your circle of competence, one tool you can use is inversion.

While there are millions of factors that go into decisions, there will always be a few variables and factors that will carry the bulk of the weight. If you're operating within your circle of competence, it should be relatively easy to figure out the relevant variables and forces at play.

I can't tell you the relevant variables. There is no magic formula. To make consistently good decisions, you need to develop a deep fluency in the area in which you are making

decisions, and you need to pull in the big ideas from multiple disciplines to make sure you're exercising good judgment.

2. The Psychological Factors

There are many causes of human misjudgment, including over-confidence. These are the subtle ways that your mind might be leading you astray at a subconscious level. Your subconscious mind is larger than your conscious mind, and yet we rarely pay attention to how we might be tricking ourselves. One way to mislead yourself, for instance, is to make decisions based on a small sample size and extrapolate the results to a larger population. Another way we fool ourselves is to remain committed to something we've said in the past. We might rely on an authority figure or default to what everyone else is doing. You get the idea.

Usually, when we have extreme success or failure, there are four or five factors working in the same direction. The same goes for psychology. The more human misjudgment factors there are working against us, the more likely we are to make an ill-informed decision.

11. Environment where you can make decisions

The Modern Office is Terrible for Thinking

No one understands how your environment shapes your ability to make decisions more than Warren Buffett and Charlie Munger. While they're gifted with intellect, they make sure they get the most out of it by structuring their environment to help them make good decisions.

Most of us make decisions in an environment where it is very hard for us to behave rationally.

You can't design a worse environment for good decisions than the modern office. When you first arrive at work, you immediately start to answer the critical emails from your swelling inbox. The inner voice in your head tells you don't worry; you'll get to the rest later. Suddenly, the phone rings, it's your boss wanting to know if you have time to chat on the 15-page proposal she was supposed to read for the meeting in 30 minutes. But you haven't read the proposal either. So you glance at the executive summary and, like anyone that has learned to survive in an office, you confidently act like you know what's going on. You haven't done the work to have an opinion. But that's the game. Everyone else did the same thing. When you finally lift your head up, your email box is swelling again, you have missed calls, and it's almost time to pick up the kids from school. Where did the day go?

This isn't an abnormal day. This is every day. From the moment you arrive until the moment you leave, you make an inch of progress on twenty things rather than ten feet of progress on one thing.

The unwritten rule is that you have to do these things to justify your job. If you're not pushing paper, firing up hundreds of emails, calling and attending meetings, and chasing something down ... just what the heck are you doing?

The cultural environment is typically about politics and signalling, not about putting people in a position to succeed. The physical environment is about busyness and distraction, not focus and thinking. Neither of these environments line up with the good decision making.

Contrast this to Warren Buffett. He has no computer in his office. He's not distracted every few minutes by that annoying little ding that signals a new email has arrived. His day isn't full of meetings. He doesn't have an annoying boss that comes around and asks him for something tangible that's he's working on. He just reads and thinks. No wonder he's so good at it.

If you want to think for yourself, you can't have someone always whispering in your ear. If you want space to think, you need quiet and calm not a bunch of smart people throwing

out new ideas. That's why Buffett moved from New York to Omaha. "In some places, it's easy to lose perspective. But I think it's very easy to keep perspective in a place like Omaha," Buffett says. He continues:

It's very easy to think clearly here. You're undisturbed by irrelevant factors and the noise generally of business investments. If you can't think clearly in Omaha, you're not going to think clearly anywhere.

Putting Buffett in a modern office is like giving Superman kryptonite. His superpowers would disappear. He wouldn't be able to think and concentrate. Luckily, he intentionally set up his environment in a way that makes it easier to behave rationally.

The (Super) Power of Environment

We influence our environments, but we forget they influence us too.

We like to believe that we are in charge that our brains are only influenced by our conscious thoughts. That sounds amazing, but it's wrong. Our conscious brain is much smaller than our subconscious brain. And yet when it comes to getting better at thinking and making decisions, we place all the emphasis on the conscious brain, learning mental models and methods of thinking that improve outcomes. In so doing, we improve the raw horsepower of our brain. Yet, there is no point having a 400 horsepower engine if you can only get 25 horsepower out of it.

Designing an Effective Environment

There is no environment that works for everyone. We all respond differently to different stimuli. A corner office on the 100th floor in New York might provide inspiration to some and distraction to others. What works for me might not work for you.

Here are three things we've found work for a lot of different people in a lot of different situations.

First, structure your day to maximize your energy. Most people do the tasks requiring the least amount of thought (answering emails, checking voicemails, catching up with people) in the morning when they are most productive. Meetings and decisions get pushed to the afternoon when our brains are not working as well. Switch your day around. Do the most important thing first.

Second, use chunks of time and be conscious when interrupting other people. Block chunks of time in your calendar for your own projects. I don't mean like 20 minutes, I mean like hours. I have every morning blocked off from 9-12. It's not easy to get into a state of flow, but once you're there, you're focused on one thing. It could be thinking about a problem in a three dimensional way or refining a report that you're writing for work. If you interrupt this time, it's expensive to get back to where you were, often taking 25 minutes or more to recover. Keep that in mind when you interrupt others.

Third, make effective behaviors easy. If there is chocolate in our office, you can be sure I'll eat it. That's why I lock the good stuff in a safe. Literally. This makes it harder to get to, and I eat less of it. OK, you probably want a better example than chocolate. Here's one I used to use at work. On the first page of my notebook at the intelligence agency, I listed some general thinking tools that I could fall back on for tough decisions. This prompted me to think through problems in a structured way and saved me from more than one mess. (Update: These are now a book).

Your Environment Matters More Than You Think.

We intuitively know that the physical and cultural environment matters.

You don't control everything in your environment, but you control enough to make a huge difference. Think about what you control and how you can change it to get more horsepower out of your brain.

12. SWOT Analysis.

- **Strength.**
- **Weakness.**
- **Opportunity.**
- **Threat.**

13. PESTLE Analysis.

- **Political.**
- **Economic.**
- **Social.**
- **Technological.**
- **Legal.**
- **Environmental.**

14. Stakeholder analysis

- **High power, highly interested people (Manage Closely):** you must fully engage these people, and make the greatest efforts to satisfy them.
- **High power, less interested people (Keep Satisfied):** put enough work in with these people to keep them satisfied, but not so much that they become bored with your message.
- **Low power, highly interested people (Keep Informed):** adequately inform these people, and talk to them to ensure that no major issues are arising. People in this category can often be very helpful with the detail of your project.
- **Low power, less interested people (Monitor):** again, monitor these people, but don't bore them with excessive communication.

15. Strategic Map (Check Online).

16. Decision Matrix.

- **Step 1-**List all of your options as the row labels on the table, and list the factors that you need to consider as the column headings. For example, if you were buying a new laptop, factors to consider might be cost, dimensions, and hard disk size.
- **Step 2-**Next, work your way down the columns of your table, scoring each option for each of the factors in your decision. Score each option from 0 (poor) to 5 (very good). Note that you do not have to have a different score for each option – if none of them are good for a particular factor in your decision, then all options should score 0.
- **Step 3-**The next step is to work out the relative importance of the factors in your decision. Show these as numbers from, say, 0 to 5, where 0 means that the factor is absolutely unimportant in the final decision, and 5 means that it is very important. (It's perfectly acceptable to have factors with the same importance.).
- **Step 4-**Now multiply each of your scores from step 2 by the values for relative importance of the factor that you calculated in step 3. This will give you weighted scores for each option/factor combination.

- **Step 5-Finally, add up these weighted scores for each of your options. The option that scores the highest wins!**

17. Pareto Analysis

Pareto analysis is premised on the idea that 80% of a project's benefit can be achieved by doing 20% of the work—or, conversely, 80% of problems can be traced to 20% of the causes. Pareto analysis is a powerful quality and decision-making tool.

Steps of Pareto Analysis

By applying the 80-20 rule, problems can be sorted based on whether they affect profits, customer complaints, technical issues, product defects, or delays and backlogs from missed deadlines. Each of these issues is given a rating based on the amount of revenue or sales, and time lost, or the number of complaints received. Here is a basic breakdown of the steps of Pareto analysis:

- Identify the problem or problems
- List or identify the cause of the issues or problems, noting that there could be multiple causes
- Score the problems by assigning a number to each one that prioritizes the problem based on the level of negative impact on the company
- Organize the problems into groups, such as [customer service](#) or system issues
- Develop and implement an action plan, focusing on the higher scored problems first, in order to solve the problems

Not all problems will have a high score, and some smaller problems may not be worth pursuing initially. By allocating resources to high-impact issues or higher scores, companies can solve problems more efficiently by targeting the issues that have a major impact on profits, sales, or customers.

How To Create a Pareto Chart

A common part of Pareto analysis is to graphically depict the occurrence of each variable being tracked. This depiction is called a Pareto chart, and it organises and displays information to show the relative importance of various problems or causes of problems. It is similar to a vertical bar graph in that it puts items in order (from the highest to the lowest) relative to some measurable effect of interest: frequency, cost, or time. Here is the process of making a Pareto chart.

- Develop a list of problems to be compared.
- Develop a standard measure for comparing the items. For example, how often it occurs: frequency (e.g., utilisation, complications, errors); how long it takes (time); how many resources it uses (cost).
- Choose a timeframe for collecting the data.
- For each item, tally how often it occurred (or cost or total time). Then, add these amounts to determine the grand total for all items.
- Find the percent of each item in the grand total by taking the sum of the item, dividing it by the grand total, and multiplying by 100.
- List the items being compared in decreasing order of the measure of comparison: e.g., the most frequent to the least frequent. The cumulative percent for an item is the sum of that item's percent of the total and that of all the other items that come before it in the ordering by rank.
- List the items on the horizontal axis of a graph from highest to lowest. Label the left vertical axis with the numbers (frequency, time, or cost).
- Label the right vertical axis with the cumulative percentages (the cumulative total should equal 100%).
- Draw in the bars for each item.
- Draw a line graph of the cumulative percentages. The first point on the line graph should line up with the top of the first bar.

The final step is analysis. You can now analyze a Pareto chart by identifying those items that appear to account for most of the difficulty. In the example below, the Institute for Healthcare Improvement identified three vital types of errors discovered during surgical set-up.

18. Cause and Effect

The diagram is called fishbone as its final look is in the form of a fishbone. It was initially used for quality improvement but it can also be helpful in analyzing business processes through the identification of its causes and hindrances, as well as on ways to improve it.

The cause and effect analysis basically involves two key steps which are looking backward and looking forward.

- In looking backward, the analysis focuses on identifying areas in which mistakes were made or money was lost. It looks into what had happened before. In identifying where the issues are, you are able to work towards avoiding the problem in the future. Another advantage of this is that, you'll be able to replicate a positive outcome.
- Looking into the future and planning for it, the analysis seeks to find workable solutions that are to be implemented in the future and build on the future success of the business. This analysis enables you to determine your future outcome by planning what to do now to achieve it.

This method is unique in that it encourages creative thinking as well as brainstorming in the process of breaking down issues and aligning them in the process of finding its solutions. Among the key advantages of this method is that it ensures that you don't seek out to solve the wrong problems, it also ensures that you solve the problem well enough for it to go away.

Step 1: Problem Identification

The way to use this tool is very simple. You first need to identify the problem area that needs analysis. A good way to do this is by giving a brief description of the current business situation and the consequences as well as the reasons for why they occurred.

Here you can replace the problem with a goal that you want to achieve. For instance, high profitability. You need to be very specific about the problem that you're facing as this forms the basis of your analysis. If the identification is wrong, then the analysis also tends to be wrong.

You should also identify the people involved as well as what the exact problem is and how it occurs. For example, low productivity due to absenteeism especially in the production department, which includes production personnel and the line manager, for the period from January to November 2017.

Step 2: Main Problem Causes

The next step is identifying the main causes of the problem, for example, the people, the procedures your business utilized as well as the materials or equipment. Here, you will need to do a lot of brainstorming to come up as many reasons as you possibly can.

You can use various models to help you **identify as many problems** as you can in a clear manner. For example, the McKinsey 7S Framework which includes, Strategy, Systems, the business Structures, Shared values of the business, Staff, Skills, and Style.

Step 3: Identify Plausible Sub-causes of the Main Causes

Thereafter, you can narrow down to further plausible causes of the main problems that you've listed. This is important for the problem-solving stage of analyzing the diagram, as you will know what to do exactly to rectify the situation. This can include issues like wrong norms and values that could be as a result of poor training of employees.

Step 4: Analyze the Diagram

By now, your diagram should be showing all the main and minor causes that you've thought of.

Depending on how complex the information is, you can do a much deeper investigation on the causes. This can be by conducting a survey as well as drawing up questionnaires.

For example, you can ask your employees to fill in a survey on how much they understand the products you sell in your business. The information you get from this will help you build upon areas of training in order to address the problem of lack or insufficient knowledge. From here, a corresponding step is developing an action plan with clear priorities that can be implemented immediately. This is made simple as the plans can comprise of actions to solve the subproblem causes.

For the action plan to be effective, it needs to be clear and to be executed aggressively. For example, a sub cause like lack of staff morale can be turned into an action plan, which will be giving incentives for **staff motivation**, hence, improved productivity and in turn higher profitability which was the main goal.

19. Force Field Analysis

How to Conduct a Force Field Analysis.

The analysis is best carried out in small groups of 5 to 9 people who are directly involved in the change implementation process.

It's important that everyone else who is also likely to be affected by the change is kept in the loop. To gain their commitment and support for the deployment of the project, they should be kept informed about and involved in planning, development and decision-making from the very beginning.

For a more productive discussion, have a force field analysis worksheet ready at the beginning of the meeting.

The worksheet can be paper-based, or you can use the following Creately template to start right away. Simply add the email addresses of the other group members to the document to give them edit/ review access. This way everyone can collaborate on populating the worksheet.

Step 1: Assess the current situation

You need to start the session by discussing the current situation of the organization in terms of the issue at hand with the key stakeholders.

This may include determining where you are at, the challenges you are facing due to the issue you are trying to solve, the reaction of the employees, etc.

It's also important to clarify where you want to go or the desired state you want to achieve with the initiative. At the same time, consider what will take place if you fail to take action to change the current situation.

Here you can do a quick [SWOT analysis](#) to understand what strengths you can use to overcome the existing threats and see how you can work on overcoming weaknesses and take advantage of the presented opportunities.

Step 2: Define the objective

The next step is to identify the expected outcome of the change initiative. Once you have clearly defined the goal(s), write them inside the box in the middle of the template provided above.

Step 3: Identify the driving forces

Driving forces are the factors that are in favor of the proposed change or the ones that support the achievement of the defined goal.

These are considered positive and usually includes factors like advancing technology, changing industry trends, increasing competition, opinions of customers or shareholders, incentives, etc.

In this step, your task is to brainstorm as many driving forces as possible with the team and list them in the relevant field of the worksheet.

Of course, you can turn to people outside the team (interview them), people who are specialised in the subject area to find the information you need during this step.

Step 4: Identify the restraining forces

These are the factors that will block your path to achieving your goal. They tend to restrict the impact of the driving forces. For example, these may include the fear of the individuals, organizational structures and negative attitudes of employees, etc.

The list of forces that are against change should be listed on the right-hand field of the worksheet.

One thing you need to keep in mind is not to be subjective when deciding which forces to add to the force field analysis and which ones to leave out.

Step 5: Evaluate the forces

You can evaluate the influence of each force by assigning them scores.

Using a numerical scale (10 being extremely strong and 1 being extremely weak), assign each force a score based on the impact they have on the change initiative.

You can also assess the forces by focusing on the impact each of them may have. This way you can ditch assigning each force a score.

Based on the effect they have, you can decide whether the proposed change is viable. Accordingly, you can discuss how you can influence the forces in favor of change: you can weaken the restricting forces by strengthening the driving forces.

Step 6: Create an action plan

Based on how you want to go about strengthening driving forces and weakening restraining forces, you can create a quick action plan.

This can help you clarify what needs to be done, who is responsible, the resources needed, and the due dates you need to be concerned about, etc.

20. Break Even Analysis.

The formula for break even analysis is as follows:

$$\text{Break Even Quantity} = \text{Fixed Costs} / (\text{Sales Price per Unit} - \text{Variable Cost Per Unit}).$$

Where:

- **Fixed Costs** are costs that do not change with varying output (e.g., salary, rent, building machinery).
- **Sales Price per Unit** is the selling price (unit selling price) per unit.
- **Variable Cost per Unit** is the variable costs incurred to create a unit.

It is also helpful to note that sales price per unit minus variable cost per unit is the **contribution margin** per unit. For example, if a book's selling price is \$100 and its variable costs are \$5 to make the book, \$95 is the contribution margin per unit and contributes to offsetting the fixed costs.

Example of Break Even Analysis

Colin is the managerial accountant in charge of Company A, which sells water bottles. He previously determined that the fixed costs of Company A consist of property taxes, a lease, and executive salaries, which add up to \$100,000. The **variable cost** associated with producing one water bottle is \$2 per unit. The water bottle is sold at a premium price of \$12. To determine the break even point of Company A's premium water bottle:

$$\text{Break Even Quantity} = \$100,000 / (\$12 - \$2) = 10,000$$

Therefore, given the fixed costs, variable costs, and selling price of the water bottles, Company A would need to sell 10,000 units of water bottles to break even.

21. Ratio Analysis.

22. Paired Comparison Analysis.

Paired Comparison Analysis is an activity for evaluating a small range of options by comparing them against each other. It is a useful and easy technique for rating and ranking alternatives where the evaluation criteria are subjective by nature. This is practically helpful when priorities are not clear enough, when alternatives are completely different from one another, or when there is little objective data to base our decision on.

Paired comparison is often used to choose the most compelling problem to solve, or to select the alternative that will be the most effective. It is useful in a wide range of applications, from selecting the concept design for a new product before it goes into production, to deciding the skills and qualifications when hiring people for a new position. Decisions like these are more difficult to make than comparing which investment to take or which vendor to select (we will select the vendor who will give us the highest quality with the best price and the fastest delivery).

Paired comparison analysis is often performed with the aid of a matrix. This matrix should be made in a way that avoids comparing an option with itself or duplicating any comparison. Two additional rows can be added to the end of the table to represent:

- The number of times each option has been selected.
- The ranking of all options based on their count.

Implementing a Paired Comparison Analysis

1. With your team, identify the options to be evaluated.
2. Identify the evaluation criterion to help you make the decision (e.g. the most important, the most interesting, or the easiest to implement).
3. List all the options on the left hand column and on the top row of the matrix.
4. In each blank cell, compare the option in the row with the option in the column, then write in the cell the option that better meets the evaluation criterion.
5. Repeat the process until all possible pairs are evaluated.
6. Count the number of times each option has been chosen.
7. Rank the options based on their count.
8. Consider the options with the highest ranking.

23. Action Priority matrix.

- 1. Quick wins (high impact, low effort)-These are tasks requiring little effort but which have a high impact. As such, they are very attractive because they have high returns for a small outlay of energy. Completing quick wins should be your highest priority, and you should concentrate on these tasks as much as you can.
- 2. Major projects (high impact, high effort)-These are tasks that can give you significant results (impact), but unlike quick wins, they require you to invest a lot of time into them. These types of tasks should be your next priority after quick wins. You'll need to invest a lot of time into these projects to get them done but be careful not to let these tasks consume all of your time.
- 3. Fill-ins (low impact, low effort)-These are tasks that require a low effort for you to perform, but they also have little impact on your results. As hinted at by the name, you use these tasks to fill in your time. You should only perform these tasks if you have the time available after working on your quick wins and major projects. Consider delegating these tasks if you have that as an option. Alternatively, consider dropping these tasks altogether if possible.
- 4. Thankless tasks (low impact, high effort)-These are tasks which have a low impact but which still require a high effort. You should aim to completely eliminate these tasks, as they are not worth your time to complete.
- To use the model, follow these four steps:

1. Make a complete list of all of your tasks.
2. Score your tasks for effort and impact. You can use any scale you like to do this, but a simple 1-10 scale works well, where one is very low, and ten is very high.
3. Place each activity in the matrix according to its effort and impact scores.
4. Prioritize your activities:
5. Give quick wins the highest priority.
6. Spend the remaining time on your major projects. You should spend the majority of your time on these tasks.
7. If you have any remaining time, do your fill-in activities. Otherwise, delegate or drop these tasks.
8. Eliminate thankless tasks. Spend absolutely zero time performing these tasks.

24. Boston Matrix

The four categories can be described as follows:

- **Stars** are **high growth products** competing in markets where they are strong compared with the competition. Often Stars need heavy investment to sustain growth. Eventually growth will slow and, assuming they keep their market share, Stars will become Cash Cows.
- **Cash cows** are **low-growth products** with a high market share. These are mature, successful products with relatively little need for investment. They need to be managed for continued profit - so that they continue to generate the strong cash flows that the company needs for its Stars.
- **Question marks** are products with low market share operating in high growth markets. This suggests that they have potential, but may need substantial investment to grow market share at the expense of larger competitors. Management have to think hard about "Question Marks" - which ones should they invest in? Which ones should they allow to fail or shrink?
- **Unsurprisingly, the term "dogs"** refers to products that have a low market share in unattractive, low-growth markets. Dogs may generate enough cash to break-even, but they are rarely, if ever, worth investing in. Dogs are usually sold or closed.

38. Ooda Loop

How the OODA Loop works: The Four Steps.

Similar to other problem-solving methods, the OODA loop is an interactive, iterative process that entails repeating the cycle, observing and measuring results, reviewing and revising the initial decision and advancing to the next step. While the process is not always simple or linear, the four separate steps involved are:

1. **Observe:** The first step is to identify the problem or threat and gain an overall understanding of the internal and external environment. In the corporate world, this can be equated to data gathering, where all of the information regarding the current organizational state, any competitors and the market is collected. The key point about the observe step is recognizing that the world is complex. All data is a snapshot in time and must be treated as such. Therefore, entities must gather whatever information is available as quickly as possible in order to be prepared to make decisions based on it.
2. **Orient:** The orientation phase involves reflecting on what has been found during observations and considering what should be done next. It requires a significant level of situational awareness and understanding in order to make a conscious decision. Since some decisions are unconscious, or instinctual, this step involves considering what and why decisions are made prior to choosing a course of action. When applied on an individual level, the orientation step can be done by creating mental models or mental rehearsal drills to place information into narratives that shape judgement. In organizational applications, situational models can be created with machine learning ([ML](#)) tools to identify potential outcomes while removing any bias.
3. **Decide:** The decision phase makes suggestions towards an action or response plan, taking into consideration all of the potential outcomes. This can be accomplished through meetings or discussions that are focused around creating a roadmap for the entire organisation.
4. **Act:** Action pertains to carrying out the decision and related changes that need to be made in response to the decision. This step may also include any testing that is required before officially carrying out an action, such as compatibility.

33. Risk Assessment Decision Tree.

34. Game theory

A. Ask: if i take action what are the consequences and how do i respond and reaction. Prisoner dilemma

35. Worst case scenario Analysis - Can you live with the worst outcome of the decision.

36. The decision does not match your values and principles. Value and Principles - Analyse if the decision aligns with your life values and principles.

37. Go get great counsel. Person should be neutral, reasonable and not emotional on topic.

38. What are your alternatives.

39. Decision fatigue. Never make massive decision when you are fatigued

40. Stick with your decision. Big decision have slow process but fast movement.

41. Taking emotions out of decisions is one key to success.

42. Benjamin Franklin Method. What works for me in terms of having an alternative is to write down the pros and cons of the decision. It's called the Benjamin Franklin method of making decisions. If the pros is greater than the cons then I will execute it. If the cons are greater then I will pass.

43. Decision Making Tools.

0. All Models Are Wrong

How is your journey towards understanding Farnam Street's latticework of mental models going? Is it proving useful? Changing your view of the world? If the answer is that it's going well that's good. There's just one tiny hitch.

All models are wrong.

Yep. It's the truth. However, there is another part to that statement:

All models are wrong; some are useful.

Those words come from the British statistician, George Box. In a groundbreaking 1976 paper, Box revealed the fallacy of our desire to categorize and organize the world. We create models (a term with many applications), once to confuse them for reality.

Box also stated:

Remember that all models are wrong; the practical question is how wrong do they have to be to not be useful.

What Exactly Is A Model?

First, we should understand precisely what a model is.

The dictionary definition states a model is 'a representation, generally in miniature, to show the construction or appearance of something' or 'a simplified description, especially a mathematical one, of a system or process, to assist calculations and predictions.'

For our purposes here, we are better served by the second definition. A model is a simplification which fosters understanding.

Think of an architectural model. These are typically a small scale model of a building, made before it's built. Its purpose is to show what the building will look like and to help people working on the project to develop a clear picture of the overall feel. In the iconic scene from Zoolander, Derek (played by Ben Stiller) looks at the architectural model of his proposed 'school for kids who can't read good' and shouts "What is this? A center for ants??"

That scene illustrates the wrong way to understand models: Too literally.

Why We Use Models- And Why They Work

At Farnam Street, we believe in using models for the purpose of building a massive, but finite amount of fundamental, invariant knowledge about how the world really works.

Applying this knowledge is the key to making good decisions and avoiding stupidity.

"Scientists generally agree that no theory is 100 percent correct. Thus, the real test of knowledge is not truth, but utility. Science gives us power. The more useful that power, the better the science."

— Yuval Noah Harari

Time-tested models allow us to understand how things work in the real world. And understanding how things work prepares us to make better decisions without expending too much mental energy in the process.

Instead of relying on fickle and specialized facts, we can learn versatile concepts.

The mental models we cover are intended to be widely applicable.

It's crucial for us to understand as many mental models as possible. As the adage goes, a little knowledge can be dangerous and creates more problems than total ignorance. No single model is universally applicable – we find exceptions for nearly everything. Even hardcore physics has not been totally solved.

"The basic trouble, you see, is that people think that "right" and "wrong" are absolute; that everything that isn't perfectly and completely right is totally and equally wrong."

— Isaac Asimov

Take a look at almost any comment section on the internet and you are guaranteed to find at least one pedant raging about a minor perceived inaccuracy, throwing out the good with

the bad. While ignorance and misinformation are certainly not laudable, neither is an obsession with perfection.

Like heuristics, models work as a consequence of the fact they are usually helpful in most situations, not because they are always helpful in a small number of situations.

Models can assist us in making predictions and forecasting the future. Forecasts are never guaranteed, yet they provide us with a degree of preparedness and comprehension of the future. For example, a weather forecast which claims it will rain today may get that wrong. Still, it's correct often enough to enable us to plan appropriately and bring an umbrella.

Mental Models and Minimum Viable Products

Think of mental models as minimum viable products.

Sure, all of them can be improved. But the only way that can happen is if we try them out, educate ourselves and collectively refine them.

We can apply one of our mental models, Occam's razor, to this. Occam's razor states that the simplest solution is usually correct. In the same way, our simplest mental models tend to be the most useful. This is because there is minimal room for errors and misapplication. *"The world doesn't have the luxury of waiting for complete answers before it takes action."*

— Daniel Gilbert

Your kitchen knives are not as sharp as they could be. Does that matter as long as they still cut vegetables? Your bed is not as comfortable as it could be. Does that matter if you can still get a good night's sleep in it? Your internet is not as fast as it could be. Does that matter as long as you can load this article? Arguably not. Our world runs on the functional, not the perfect. This is what a mental model is – a functional tool. A tool which maybe could be a bit sharper or easier to use, but still does the job.

The statistician David Hand made the following statement in 2014;

In general, when building statistical models, we must not forget that the aim is to understand something about the real world. Or predict, choose an action, make a decision, summarize evidence, and so on, but always about the real world, not an abstract mathematical world: our models are not the reality.

For example, in 1960, Georg Rasch said the following:

When you construct a model you leave out all the details which you, with the knowledge at your disposal, consider inessential.... Models should not be true, but it is important that they are applicable, and whether they are applicable for any given purpose must, of course, be investigated. This also means that a model is never accepted finally, only on trial.

Imagine a world where physics like precision is prized over usefulness.

We would lack medical care because a medicine or procedure can never be perfect. In a world like this, we would possess little scientific knowledge, because research can never be 100% accurate. We would have no art because a work can never be completed. We would have no technology because there are always little flaws which can be ironed out.

"A model is a simplification or approximation of reality and hence will not reflect all of reality ... While a model can never be "truth," a model might be ranked from very useful, to useful, to somewhat useful to, finally, essentially useless."

— Ken Burnham and David Anderson

In short, we would have nothing. Everything around us is imperfect and uncertain. Some things are more imperfect than others, but issues are always there. Over time, incremental improvements happen through unending experimentation and research.

The Map is Not the Territory

As we know, the map is not the territory. A map can be seen as a symbol or index of a place, not an icon.

When we look at a map of Paris, we know it is a representation of the actual city. There are bound to be flaws; streets which have been renamed, demolished buildings, perhaps a new Metro line. Even so, the map will help us find our way. It is far more useful to have a map showing the way from Notre Dame to Gare du Nord (a tool) than to know how many meters they are apart (a piece of trivia.)

Someone who has spent a lot of time studying a map will be able to use it with greater ease, just like a mental model. Someone who lives in Paris will find the map easier to understand than a tourist, just as someone who uses a mental model in their day to day life will apply it better than a novice. As long as there are no major errors, we can consider the map useful, even if it is by no means a reflection of reality. Gregory Bateson writes in Steps to an Ecology of Mind that the purpose of a map is not to be true, but to have a structure which represents truth within the current context.

“A map is not the territory it represents, but, if correct, it has a similar structure to the territory, which accounts for its usefulness.”

— Alfred Korzybski

Physical maps generally become more accurate as time passes. Not long ago, they often included countries which didn't exist, omitted some which did, portrayed the world as flat or fudged distances. Nowadays, our maps have come a long way.

The same goes for mental models – they are always evolving, being revised – never really achieving perfection. Certainly, over time, the best models are revised only slightly, but we must never consider our knowledge “set”.

Another factor to consider in using models is to take into account what they're used for. Many mental models (e.g. entropy, critical mass and activation energy) are based upon scientific and mathematical concepts. A person who works in those areas will obviously need a deeper understanding of it than someone who want to learn to think better when making investment decisions. They will need a different map and a more detailed one showing elements which the rest of us have no need for.

“A model which took account of all the variation of reality would be of no more use than a map at the scale of one to one.”

— Joan Robinson

In his essay *Partial Enchantments of the Quixote*, Jorge Luis Borges provides an even more interesting analysis of the confusion between models and reality:

Let us imagine that a portion of the soil of England has been leveled off perfectly and that on it a cartographer traces a map of England. The job is perfect; there is no detail of the soil of England, no matter how minute that is not registered on the map; everything has there its correspondence. This map, in such a case, should contain a map of the map, which should contain a map of the map of the map, and so on to infinity. Why does it disturb us that the map be included in the map and the thousand and one nights in the book of the Thousand and One Nights? Why does it disturb us that Don Quixote be a reader of the Quixote and Hamlet a spectator of Hamlet? I believe I have found the reason: these inversions suggest that if the characters of a fictional work can be readers or spectators, we, its readers or spectators, can be fictions.

How Do We Know If A Model Is Useful?

This is a tricky question to answer. When looking at any model, it is helpful to ask some of the following questions:

- How long has this model been around? As a general rule, mental models which have been around for a long time (such as Occam's razor) will have been subjected to a great deal of scrutiny. Time is an excellent curator, trimming away inefficient ideas. A mental model which is new may not be particularly refined or versatile.

Many of our mental models originate from Ancient Greece and Rome, meaning they have to be functional to have survived this long.

- Is it a representation of reality? In other words, does it reflect the real world? Or is it based on abstractions?
- Does this model apply to multiple areas? The more elastic a model is, the more valuable it is to learn about. (Of course, be careful not to apply the model where it doesn't belong. Mind Feynman: "You must not fool yourself, and you're the easiest person to fool.")
- How did this model originate? Many mental models arise from scientific or mathematical concepts. The more fundamental the domain, the more likely the model is to be true and lasting.
- Is it based on first principles? A first principle is a foundational concept which cannot be deduced from any other concept and must be known.
- Does it require infinite regress? Infinite regress refers to something which is justified by principles, which themselves require justification by other principles. A model based on infinite regress is likely to require extensive knowledge of a particular topic, and have minimal real-world application.

When using any mental model, we must avoid becoming too rigid. There are exceptions to all of them, and situations in which they are not applicable.

Think of the latticework as a toolkit. That's why it pays to do the work up front to put so many of them in your toolbox at a deep, deep level. If you only have one or two, you're likely to attempt to use them in places that don't make sense. If you've absorbed them only lightly, you will not be able to use them when the time is at hand.

If on the other hand, you have a toolbox full of them and they're sunk in deep, you're more likely to pull out the best ones for the job exactly when they are needed.

Too many people are caught up wasting time on physics-like precision in areas of practical life that do not have such precision available. A better approach is to ask "Is it useful?" and, if yes, "To what extent?"

Mental models are a way of thinking about the world that prepares us to make good decisions in the first place.

0B. Mental Models (Use mental models).

1. The Anatomy of a Decision: An Introduction to Decision Making

“The only proven way to raise your odds of making a good decision is to learn to use a good decision-making process—one that can get you the best solution with a minimal loss of time, energy, money, and composure.”

— John Hammond

This is an introduction to decision making.

A good decision-making process can literally change the world.

Consider the following example from Predictable Surprises: In 1962, when spy planes spotted Soviet missiles in Cuba, U.S. military leaders urged President Kennedy to authorize an immediate attack. Fresh from the bruising failure of the Bay of Pigs, Kennedy instead set up a structured decision-making process to evaluate his options. In a precursor of the Devil's Advocacy method, Kennedy established two groups each including government officials and outside experts, to develop and evaluate the two main options—attack Cuba or set up a blockade to prevent more missiles from reaching its shores. Based on the groups' analysis and debate, Kennedy decided to establish a blockade. The Soviets backed down, and nuclear war was averted. Recently available documents suggest that if the United States had invaded Cuba, the consequences would have been catastrophic: Soviet missiles that had not been located by U.S. Intelligence could still have struck several U.S. cities.

The concept of a decision-making process can be found in the early history of thinking.

Decisions should be the result of rational and deliberate reasoning.

Plato argues that human knowledge can be derived based on reason alone using deduction and self-evident propositions. Aristotle formalized logic with logical proofs where someone could reasonably determine if a conclusion was true or false.

However, as we will discover, not all decisions are perfectly rational. Often, we let our system one thinking—intuition—make decisions for us. Our intuition is based on long-term memory that has been primarily acquired over the years through learning and allows our mind to process and judge without conscious awareness. System one thinking, however, does not always lead to optimal solutions and often tricks our mind to thinking that consequences and second-order effects are either non-existent or less probable than reality would indicate.

In Predictable Surprises Max Bazerman writes:

Rigorous decision analysis combines a systematic assessment of the probabilities of future events with a hard-headed evaluation of the costs and benefits of particular outcomes. As such, it can be an invaluable tool in helping organizations overcome the biases that hinder them in estimating the likelihood of unpleasant events. Decision analysis begins with a clear definition of the decision to be made, followed by an explicit statement of objectives and explicit criteria for assessing the “goodness” of alternative courses of action, by which we mean the net cost or benefit as perceived by the decision-maker. The next steps involve identifying potential courses of action and their consequences. Because these elements often are laid out visually in a decision tree, this technique is known as “decision tree analysis.” Finally, the technique instructs decision-makers to explicitly assess and make trade-offs based on the potential costs and benefits of different courses of action.

To conduct a proper decision analysis, leaders must carefully quantify costs and benefits, their tolerance for accepting risk, and the extent of uncertainty associated with different potential outcomes. These assumptions are inherently subjective, but the process of quantification is nonetheless extremely valuable' it forces participants to express their

assumptions and beliefs, thereby making them transparent and subject to challenge and improvement.

From Judgment in Management Decision Making by Max Bazerman:

The term judgment refers to the cognitive aspects of the decision-making process. To fully understand judgment, we must first identify the components of the decision-making process that require it.

Let's look at six steps you should take, either implicitly or explicitly, when applying a "rational" decision-making process to each scenario.

1. Define the problem. (M)anagers often act without a thorough understanding of the problem to be solved, leading them to solve the wrong problem. Accurate judgment is required to identify and define the problem. Managers often err by (a) defining the problem in terms of a proposed solution, (b) missing a bigger problem, or (c) diagnosing the problem in terms of its symptoms. Your goal should be to solve the problem not just eliminate its temporary symptoms.

2. Identify the criteria. Most decisions require you to accomplish more than one objective. When buying a car, you may want to maximize fuel economy, minimize cost, maximize comfort, and so on. The rational decision maker will identify all relevant criteria in the decision-making process.

3. Weight the criteria. Different criteria will vary in importance to a decision maker. Rational decision makers will know the relative value they place on each of the criteria identified. The value may be specified in dollars, points, or whatever scoring system makes sense.

4. Generate alternatives. The fourth step in the decision-making process requires identification of possible courses of action. Decision makers often spend an inappropriate amount of search time seeking alternatives, thus creating a barrier to effective decision making. An optimal search continues only until the cost of the search outweighs the value of added information.

5. Rate each alternative on each criterion. How well will each of the alternative solutions achieve each of the defined criteria? This is often the most difficult stage of the decision-making process, as it typically requires us to forecast future events. The rational decision maker carefully assesses the potential consequences on each of the identified criteria of selecting each of the alternative solutions.

6. Compute the optimal decision. Ideally, after all of the first five steps have been completed, the process of computing the optimal decision consists of (a) multiplying the ratings in step 5 by the weight of each criterion, (b) adding up the weighted ratings across all of the criteria for each alternative, and (c) choosing the solution with the highest sum of weighted ratings.

Hammond, Keeney, and Raiffa suggest 8 steps in their book Smart Choices:

- 1. Work on the right problem.*
- 2. Identify all criteria.*
- 3. Create imaginative alternatives.*
- 4. Understand the consequences.*
- 5. Grapple with your tradeoffs.*
- 6. Clarify your uncertainties.*
- 7. Think hard about your risk tolerance.*
- 8. Consider linked decisions.*

* * *

People, however, are not always entirely logical machines. In Judgment in Managerial Decision Making, the distinction between System One and System Two thinking becomes clear:

System 1 thinking refers to our intuitive system, which is typically fast, automatic, effortless, implicit, and emotional. We make most decisions in life using System 1 thinking. For instance, we usually decide how to interpret verbal language or visual information

automatically and unconsciously. By contrast, System 2 refers to reasoning that is slower, conscious, effortful, explicit, and logical. System 2 thinking can be broken down into (1) define the problem; (2) identify the criteria; (3) weigh the criteria; (4) generate alternatives; (5) rate each alternative on each criterion; (6) compute the optimal decision. In most situations, our system 1 thinking is quite sufficient; it would be impractical, for example, to logically reason through every choice we make while shopping for groceries. But System 2 logic should preferably influence our most important decisions.

* * *

When making a decision, we are psychologically influenced either consciously or unconsciously. By exploring these biases and other elementary, worldly wisdom, we hope to make you a better decision-maker.

Following a rational decision process can help us focus on outcomes that are low in probability but high in potential costs. Without easily quantifiable costs, we often dismiss low probability events or fall prey to biases. We don't want to be the fragilista.

Even rational decision-making processes like the one presented above make several assumptions. The first assumption is that a rational decision-maker is completely informed which means they know about all the possible options and outcomes. The second major assumption is that the decision-maker does not fall prey to any biases that might impact the rational decision.

In researching decision-making processes, it struck us as odd that few people question the information upon which criteria are measured. For instance, if you are purchasing a car and use fuel efficiency as the sole criterion for decision making, you would need to make sure that the cars under consideration were all tested and measured fuel consumption in the same way. This second order of thinking can help you make better decisions.

If you want to make better decisions, you should read Judgment in Managerial Decision Making. That is the best book I've come across on decision making. If you know of a better one, please send me an email.

Stanovich's book, What Intelligence Tests Miss: The Psychology of Rational Thought, proposes a whole range of cognitive abilities and dispositions independent of intelligence that have at least as much to do with whether we think and behave rationally.

2. The Psychology of Pirates: How to Choose a Ransom

Reading The Invisible Hook really got me *hooked* on learning more about pirates.

How do pirates decide what ransom to ask for?

The answer, from an interview with an actual pirate, might surprise you. Despite what many think, they are very smart and intuitively grasp governance, incentives, and other aspects of human nature. This interview touches on incentives, reinforcement, moral hazard, and anchoring.

How do you pirates decide on what ransom to ask for?

Once you have a ship, it's a win-win situation. We attack many ships everyday, but only a few are ever profitable. No one will come to the rescue of a third-world ship with an Indian or African crew, so we release them immediately. But if the ship is from Western country or with valuable cargo like oil, weapons or then its like winning a lottery jackpot. We begin asking a high price and then go down until we agree on a price.

How do you know a ship in far away coast in the first place and its flagship?

Often we know about a ship's cargo, owners and port of origin before we even board it. That way we can price our demands based on its load. For those with very valuable cargo on board then we contact the media and publicize the capture and put pressure on the companies to negotiate for its release.

From what I've seen, initial demands tend to be about 10 times the previous publicized ransom, is this a rule of thumb?

We know that we won't get our initial demands, but we use it as a starting point and negotiate downwards to our eventual target. But as a rule, yes, that's about right.

Does the length of a hijacking change the ransom that pirates are willing to accept?

Yes. Armed men are expensive as are the laborers, accountants, cooks and khat suppliers on land. During long negotiations our men get tired and we need to rotate them out three times a week. Add to that the risk from navies attacking us and we can be convinced to lower our demands.

What are the key factors to making a successful attack on a ship?

The key to our success is that we are willing to die, and the crews are not. Beyond that, in my case deploy a boat with six men to get close to the ship and leave another in reserve near the coast just in case we need backup. We use sophisticated equipment that allows us to spot our targets from a distance. We always have to be close to the main sea lane and keep in touch with each other using talkie phones.

How much does it cost to outfit a pirate mission?

A single mission with 12 armed men and boats costs a little over \$30,000. But a successful investor has to dispatch at least three or four missions to get lucky once.

How are the pirates organized? (Are there pirate leaders, financiers, and specialists?)

The financiers are the most important since they organize and plan the big shot operations and are able to pay running cost[s]. Financiers always need to forge deals with traders, land cruiser owners, translators, business people to keep the supplies flowing during operations and manage the logistics. There is a long supply chain involved in every hijacking.

Are there internal conflicts within the pirate gangs?

No. In piracy, everyones' life depends on everyone else's. There is some professional competition between groups, but we cooperate with information and logistics when it's required. We won't fight amongst ourselves as long as the money is paid as promised. We have never had any conflicts within my group.

3. The Principles of Comparative Advantage: Why Tiger Woods Shouldn't Mow Your Lawn

In economics, comparative advantage refers to the ability of a person or nation to produce a good or service at a lower opportunity cost than another person (or nation). This is why trade can create value for both parties—because each person can concentrate on the activity for which they have the lower opportunity cost. It also explains why Tiger Woods shouldn't mow your lawn.

The term “comparative advantage” is usually attributed to David Ricardo. In his 1817 book On The Principles Of Political Economy And Taxation, Ricardo used the example of trade between England and Portugal.

Portugal could produce both wine and cloth with less labor than it would have taken to produce the same output in England. However, the relative costs are different (currencies have different values). From Ricardo's point of view, England had difficulty producing wine and very little difficulty producing cloth. Portugal, however, could easily produce both wine and cloth. Ricardo concluded that while it was cheaper to produce cloth in Portugal than England, it is cheaper still for Portugal to produce excess wine and trade this for English cloth. England would benefit from this trade because its cost of producing cloth has not changed but it can now get wine at a lower price. Thus, each country can gain by specializing in the good that has a comparative advantage.

One of the drawbacks of trade in this way is that it creates increasing interdependence among people or nations. In Ricardo's example, England and Portugal relied on each other for certain goods. This is possible as long as it is in the self-interest of each nation and there are no disruptions.

In the leading economics textbook, Principles of Microeconomics, Greg Mankiw offers the following:

Differences in opportunity cost and comparative advantage create the gains from trade. When each person specializes in producing the good for which he or she has a comparative advantage, total production in the economy rises, and this increase in the size of the economic pie can be used to make everyone better off. In other words, as long as two people have different opportunity costs, each can benefit from trade by obtaining a good at a lower price than his or her opportunity cost of that good.

Real Life Examples

Should Tiger Woods Mow His Own Lawn?

Tiger is a great athlete. One of the best golfers to have ever lived. Most likely he is better at other activities too. Tiger is probably in better shape than most: He can run faster, lift more, and work quicker. For example, Tiger can probably mow his lawn faster than anyone else. But just because he can mow his lawn fast, does this mean he should?

To answer this question we can use the concepts of opportunity cost and comparative advantage. Let's say that Tiger can mow his lawn in 2 hours. In the same two hours he could film a television commercial for golf clubs and earn \$100,000. By contrast, Joe, the kid next door can mow Tiger's lawn in 4 hours. In that same 4 hours he could work at McDonald's and earn \$24.

In this example, Tiger's opportunity cost is \$100,000 and Joe's is \$24. Tiger has an absolute advantage in mowing lawns because he can do the work in less time. Yet Joe has a comparative advantage because he has the lower opportunity cost. The gains in trade from this example are tremendous. Rather than mowing his own lawn, Tiger should make the commercial and hire Joe to mow his lawn. As long as Tiger pays Joe more than \$24 and less than \$100,000, both of them are better off.

(Another example, this one from wikipedia)

Two men live alone on an isolated island. To survive they must undertake a few basic economic activities like water carrying, fishing, cooking and shelter construction and maintenance. The first man is young, strong, and educated. He is also, faster, better, more productive at everything. He has an absolute advantage in all activities. The second man is old, weak, and uneducated. He has an absolute disadvantage in all economic activities. In some activities the difference between the two is great; in others it is small. Despite the fact that the younger man has absolute advantage in all activities, it is not in the interest of either of them to work in isolation since they both can benefit from specialization and exchange. If the two men divide the work according to comparative advantage then the young man will specialize in tasks at which he is most productive, while the older man will concentrate on tasks where his productivity is only a little less than that of a young man. Such an arrangement will increase total production for a given amount of labor supplied by both men and it will make both of them richer.

4. Social Dilemmas: When to Defect and When to Cooperate

Social dilemmas arise when an individual receives a higher payoff for defecting than cooperating when everyone else cooperates. When everyone defects they are worse off. That is, each member has a clear and unambiguous incentive to make a choice, which if made by all members provides a worse outcome.

A great example of a social dilemma is to imagine yourself out with a group of your friends for dinner. Before the meal, you all agree to share the cost equally. Looking at the menu you see a lot of items that appeal to you but are outside of your budget.

Pondering on this, you realize that you're only on the hook for $1/(\text{number of friends at the dinner})$ of the bill. Now you can enjoy yourself without having to pay the full cost.

But what if everyone at the table realized the same thing? My guess is you'd all be stunned by the bill, even the tragedy of the commons.

This is a very simple example but you can map this to the business world by thinking about healthcare and insurance.

If that sounds a lot like game theory, you're on the right track.

I came across an excellent paper[1] by Robyn Dawes and David Messick, which takes a closer look at social dilemmas.

A Psychological Analysis of Social Dilemmas

In the case of the public good, one strategy that has been employed is to create a moral sense of duty to support it—for instance, the public television station that one watches.

The attempt is to reframe the decision as doing one's duty rather than making a difference—again, in the wellbeing of the station watched. The injection of a moral element changes the calculation from “Will I make a difference” to “I must pay for the benefit I get.”

The final illustration, the shared meal and its more serious counterparts, requires yet another approach. Here there is no hierarchy, as in the organizational example, that can be relied upon to solve the problem. With the shared meal, all the diners need to be aware of the temptation that they have and there need to be mutually agreed-upon limits to constrain the diners. Alternatively, the rule needs to be changed so that everyone pays for what they ordered. The latter arrangement creates responsibility in that all know that they will pay for what they order. Such voluntary arrangements may be difficult to arrange in some cases. With the medical insurance, the insurance company may recognize the risk and insist on a principle of co-payments for medical services. This is a step in the direction of paying for one's own meal, but it allows part of the “meal” to be shared and part of it to be paid for by the one who ordered it.

The fishing version is more difficult. To make those harvesting the fish pay for some of the costs of the catch would require some sort of taxation to deter the unbridled exploitation of the fishery. Taxation, however, leads to tax avoidance or evasion. But those who harvest the fish would have no incentive to report their catches accurately or at all, especially if they were particularly successful, which simultaneously means particularly successfully—compared to others at least—in contributing to the problem of a subsequently reduced yield. Voluntary self-restraint would be punished as those with less of that personal quality would thrive while those with more would suffer. Conscience, as Hardin (1968) noted, would be self-eliminating. ...

Relatively minor changes in the social environment can induce major changes in decision making because these minor changes can change the perceived appropriateness of a situation. One variable that has been shown to make such a difference is whether the decision maker sees herself as an individual or as a part of a group.

5. Warren Buffett and the Power of Nontransitive Dice

In a terrific book by William Poundstone, Fortune's Formula: The Untold Story of the Scientific Betting System that Beat the Casinos and Wall Street, is the story of a 1968 dinner meeting between mathematician Edward Thorp and fund manager Warren Buffett. Poundstone casually mentions that Buffett and Thorpe discussed their shared interest in nontransitive dice.

"These are," writes Poundstone, "a mathematical curiosity, a type of 'trick' dice that confound most people's ideas about probability."

Ivars Peterson describes nontransitive dice on the Mathematical Association of America's website:

The game involves four specially numbered dice. You let your opponent pick any one of the four dice. You choose one of the remaining three dice. Each player tosses his or her die, and the higher number wins the throw. Amazingly, in a game involving 10 or more throws, you will nearly always have more wins.

Here's what the dice look like:

The trick is to always let your opponent pick first, and then you pick the die to the left of his selection (if he picks the die with the four 4s, then circle round to the die with the three ones). It's just like playing Rock, Paper, Scissors — only you get to see what the other guy picks in advance.

With these dice, you always have a $2/3$ probability of winning — what a great sucker's bet!

6. Three Questions to Remove Ego from Decision Making

Here are three questions leaders can ask to help make better decisions.

1. How will this decision make things better for the organization?

Consider how the decision will affect the organization's ability to fulfill its mission.

Managers who push their teams to achieve "stretch goals" without providing adequate support and resources may be seeking to get noticed by their bosses rather than helping the company serve its customers. Such behavior will have another side effect — talent will exit. The answer to this question must enhance the organization, not simply the resume of the manager.

2. How will this decision affect employees?

The business case for your decision should factor in the people quotient and affects on headcount, training, and development. Employees must execute what leaders decide, so if employees perceive that their boss is only doing something to make himself look good, they'll be reluctant to embrace the change. They may comply, but they may never commit unless they determine the benefit for themselves.

3. How will this decision affect me?

When you are involved in a project, it is easy to entangle ego with outcome. Healthy ego is necessary, but when too much ego makes a you blind to obvious problems such as lack of resources, customer disinterest, and employee morale, problems arise. As we have seen with corporate executives in the financial sector, it isn't positive when personal interest comes before corporate and public interest. So if the answer to this question is more in favor of you rather than the company, the issue may be over-personalized and need more deliberation.

7. The Famous Game Show Problem

Ahh, the famous game show problem (also known as The Monty Hall Problem).

This is a probability puzzle you've heard of:

Suppose you're on a game show, and you're given the choice of three doors. Behind one door is a car, behind the others, goats. You pick a door, say #1, and the host, who knows what's behind the doors, opens another door, say #3, which has a goat. He says to you, "Do you want to pick door #2?" Is it to your advantage to switch your choice of doors?

Marilyn Vos Savant, one of the "smartest" people in the world, offers her answer:

When you switch, you win 2/3 of the time and lose 1/3, but when you don't switch, you only win 1/3 of the time and lose 2/3. You can try it yourself and see.....

The winning odds of 1/3 on the first choice can't go up to 1/2 just because the host opens a losing door. To illustrate this, let's say we play a shell game. You look away, and I put a pea under one of three shells. Then I ask you to put your finger on a shell. The odds that your choice contains a pea are 1/3, agreed? Then I simply lift up an empty shell from the remaining other two. As I can (and will) do this regardless of what you've chosen, we've learned nothing to allow us to revise the odds on the shell under your finger.

The benefits of switching are readily proven by playing through the six games that exhaust all the possibilities. For the first three games, you choose #1 and "switch" each time, for the second three games, you choose #1 and "stay" each time, and the host always opens a loser.

8. In The Arena: Citizenship In A Republic

It is not the critic who counts: not the man who points out how the strong man stumbles or where the doer of deeds could have done better. The credit belongs to the man who is actually in the arena, whose face is marred by dust and sweat and blood, who strives valiantly, who errs and comes up short again and again, because there is no effort without error or shortcoming, but who knows the great enthusiasms, the great devotions, who spends himself for a worthy cause; who, at the best, knows, in the end, the triumph of high achievement, and who, at the worst, if he fails, at least he fails while daring greatly, so that his place shall never be with those cold and timid souls who knew neither victory nor defeat.

Theodore Roosevelt

I grew up thinking that avoiding criticism was good. Perhaps you did too. But as an adult, I know that's not really what I want.

Every day we make a choice. We can either sit in the stands with the crowd shouting at the people on the field doing the work, or we can jump down from the stand and onto the field.

Sitting in the stands is safe. We rarely look like a fool in the comfort of the masses. The cost of this comfort is that we never really do anything. Choosing to run onto the field and play means we might look like a fool in front of thousands but offers us the chance to do something worthwhile. Surely you want to be on the field. I do. Sure, it's not always fun or comfortable. But given the choices, it's obvious which is better.

So much advantage in life comes from being willing to look like an idiot over the short term.

In *Rising Strong*, Brene Brown comments on Roosevelt's speech, focusing on one particular part: "*The credit belongs to the man who is actually in the arena, whose face is marred by dust and sweat and blood.*" She writes —

We're facedown in the arena. Maybe the crowd has gone silent, the way it does at football games or my daughter's field hockey matches when the players on the field take a knee because someone is hurt. Or maybe people have started booing and jeering. Or maybe you have tunnel vision and all you can hear is your parent screaming, "Get up! Shake it off!"

Our "facedown" moments can be big ones like getting fired or finding out about an affair, or they can be small ones like learning a child has lied about her report card or experiencing a disappointment at work. Arenas always conjure up grandeur, but an arena is any moment when or place where we have risked showing up and being seen. Risking being awkward and goofy at a new exercise class is an arena. Leading a team at work is an arena. A tough parenting moment puts us in the arena. Being in love is definitely an arena. [...]

On a cultural level, I think the absence of honest conversation about the hard work that takes us from lying facedown in the arena to rising strong has led to two dangerous outcomes: the propensity to gold-plate grit and a badassery deficit.

My first year playing football in high school, I was forced to sit on the bench. It killed me to watch my teammates battle it out while I was on the sideline. Most parents would shout at the people on the field, telling them how they were messing up and what they couldn't see. I remember listening to them one game and wanting them to yell at me. If they were yelling at me, it meant I was playing. I was getting dirty and battling it out. I'd rather be exhausted, face down in the mud at the end of a game we lost, than sit with a clean jersey on the sidelines with no responsibility.

Once you develop that mindset, it stays with you forever.

After University, I joined a three-letter intelligence agency and wanted to be in operations. I wanted to be the one making the call. I didn't want to absolve myself of responsibility or accountability. I wanted the weight on my shoulders. I didn't want to helplessly watch someone else carrying it.

Not much has changed since then. As an entrepreneur, I'm the arena building every day. When you have millions of readers, people are going to shout. When you start a new business, which I'm about to do for the fourth time, people will laugh when you stumble. I'd be more upset if there was silence. If no one is criticizing you, it means you're not doing anything worth doing.

That's not to say you should ignore all criticism. That's too simplistic. Turn down the volume on the people who haven't done what you're trying to do or aren't in the arena with you. Turn up the volume on the people who've done it before.

9. Seth Klarman: The Forgotten Lessons of 2008

In this excerpt from his annual letter, investing great Seth Klarman describes 20 lessons from the financial crisis which, he says, “were either never learned or else were immediately forgotten by most market participants.”

* * *

The Forgotten Lessons of 2008

One might have expected that the near-death experience of most investors in 2008 would generate valuable lessons for the future. We all know about the “depression mentality” of our parents and grandparents who lived through the Great Depression. Memories of tough times colored their behavior for more than a generation, leading to limited risk taking and a sustainable base for healthy growth. Yet one year after the 2008 collapse, investors have returned to shockingly speculative behavior. One state investment board recently adopted a plan to leverage its portfolio – specifically its government and high-grade bond holdings – in an amount that could grow to 20% of its assets over the next three years. No one who was paying attention in 2008 would possibly think this is a good idea.

Below, we highlight the lessons that we believe could and should have been learned from the turmoil of 2008. Some of them are unique to the 2008 melt- down; others, which could have been drawn from general market observation over the past several decades, were certainly reinforced last year. Shockingly, virtually all of these lessons were either never learned or else were immediately forgotten by most market participants.

Twenty Investment Lessons of 2008

1. Things that have never happened before are bound to occur with some regularity. You must always be prepared for the unexpected, including sudden, sharp downward swings in markets and the economy. Whatever adverse scenario you can contemplate, reality can be far worse.
2. When excesses such as lax lending standards become widespread and persist for some time, people are lulled into a false sense of security, creating an even more dangerous situation. In some cases, excesses migrate beyond regional or national borders, raising the ante for investors and governments. These excesses will eventually end, triggering a crisis at least in proportion to the degree of the excesses. Correlations between asset classes may be surprisingly high when leverage rapidly unwinds.
3. Nowhere does it say that investors should strive to make every last dollar of potential profit; consideration of risk must never take a backseat to return. Conservative positioning entering a crisis is crucial: it enables one to maintain long-term oriented, clear thinking, and to focus on new opportunities while others are distracted or even forced to sell. Portfolio hedges must be in place before a crisis hits. One cannot reliably or affordably increase or replace hedges that are rolling off during a financial crisis.
4. Risk is not inherent in an investment; it is always relative to the price paid. Uncertainty is not the same as risk. Indeed, when great uncertainty – such as in the fall of 2008 – drives securities prices to especially low levels, they often become less risky investments.
5. Do not trust financial market risk models. Reality is always too complex to be accurately modeled. Attention to risk must be a 24/7/365 obsession, with people – not computers – assessing and reassessing the risk environment in real time. Despite the predilection of some analysts to model the financial markets using sophisticated mathematics, the markets are governed by behavioral science, not physical science.
6. Do not accept principal risk while investing short-term cash: the greedy effort to earn a few extra basis points of yield inevitably leads to the incurrence of greater

risk, which increases the likelihood of losses and severe illiquidity at precisely the moment when cash is needed to cover expenses, to meet commitments, or to make compelling long-term investments.

7. The latest trade of a security creates a dangerous illusion that its market price approximates its true value. This mirage is especially dangerous during periods of market exuberance. The concept of “private market value” as an anchor to the proper valuation of a business can also be greatly skewed during ebullient times and should always be considered with a healthy degree of skepticism.
8. A broad and flexible investment approach is essential during a crisis. Opportunities can be vast, ephemeral, and dispersed through various sectors and markets. Rigid silos can be an enormous disadvantage at such times.
9. You must buy on the way down. There is far more volume on the way down than on the way back up, and far less competition among buyers. It is almost always better to be too early than too late, but you must be prepared for price markdowns on what you buy.
10. Financial innovation can be highly dangerous, though almost no one will tell you this. New financial products are typically created for sunny days and are almost never stress-tested for stormy weather. Securitization is an area that almost perfectly fits this description; markets for securitized assets such as subprime mortgages completely collapsed in 2008 and have not fully recovered. Ironically, the government is eager to restore the securitization markets back to their pre-collapse stature.
11. Ratings agencies are highly conflicted, unimaginative dupes. They are blissfully unaware of adverse selection and moral hazard. Investors should never trust them.
12. Be sure that you are well compensated for illiquidity – especially illiquidity without control – because it can create particularly high opportunity costs.
13. At equal returns, public investments are generally superior to private investments not only because they are more liquid but also because amidst distress, public markets are more likely than private ones to offer attractive opportunities to average down.
14. Beware leverage in all its forms. Borrowers – individual, corporate, or government – should always match fund their liabilities against the duration of their assets. Borrowers must always remember that capital markets can be extremely fickle, and that it is never safe to assume a maturing loan can be rolled over. Even if you are unleveraged, the leverage employed by others can drive dramatic price and valuation swings; sudden unavailability of leverage in the economy may trigger an economic downturn.
15. Many LBOs are man-made disasters. When the price paid is excessive, the equity portion of an LBO is really an out-of-the-money call option. Many fiduciaries placed large amounts of the capital under their stewardship into such options in 2006 and 2007.
16. Financial stocks are particularly risky. Banking, in particular, is a highly leveraged, extremely competitive, and challenging business. A major European bank recently announced the goal of achieving a 20% return on equity (ROE) within several years. Unfortunately, ROE is highly dependent on absolute yields, yield spreads, maintaining adequate loan loss reserves, and the amount of leverage used. What is the bank’s management to do if it cannot readily get to 20%? Leverage up? Hold riskier assets? Ignore the risk of loss? In some ways, for a major financial institution even to have a ROE goal is to court disaster.
17. Having clients with a long-term orientation is crucial. Nothing else is as important to the success of an investment firm.
18. When a government official says a problem has been “contained,” pay no attention.

19. The government – the ultimate short- term-oriented player – cannot with- stand much pain in the economy or the financial markets. Bailouts and rescues are likely to occur, though not with sufficient predictability for investors to comfortably take advantage. The government will take enormous risks in such interventions, especially if the expenses can be conveniently deferred to the future. Some of the price-tag is in the form of back- stops and guarantees, whose cost is almost impossible to determine.
20. Almost no one will accept responsibility for his or her role in precipitating a crisis: not leveraged speculators, not willfully blind leaders of financial institutions, and certainly not regulators, government officials, ratings agencies or politicians.

Below, we itemize some of the quite different lessons investors seem to have learned as of late 2009 – false lessons, we believe. To not only learn but also effectively implement investment lessons requires a disciplined, often contrary, and long-term-oriented investment approach. It requires a resolute focus on risk aversion rather than maximizing immediate returns, as well as an understanding of history, a sense of financial market cycles, and, at times, extraordinary patience.

False Lessons

1. There are no long-term lessons – ever.
2. Bad things happen, but really bad things do not. Do buy the dips, especially the lowest quality securities when they come under pressure, because declines will quickly be reversed.
3. There is no amount of bad news that the markets cannot see past.
4. If you've just stared into the abyss, quickly forget it: the lessons of history can only hold you back.
5. Excess capacity in people, machines, or property will be quickly absorbed.
6. Markets need not be in sync with one another. Simultaneously, the bond market can be priced for sustained tough times, the equity market for a strong recovery, and gold for high inflation. Such an apparent disconnect is indefinitely sustainable.
7. In a crisis, stocks of financial companies are great investments, because the tide is bound to turn. Massive losses on bad loans and soured investments are irrelevant to value; improving trends and future prospects are what matter, regardless of whether profits will have to be used to cover loan losses and equity shortfalls for years to come.
8. The government can reasonably rely on debt ratings when it forms programs to lend money to buyers of otherwise unattractive debt instruments.
9. The government can indefinitely control both short-term and long-term interest rates.
10. The government can always rescue the markets or interfere with contract law whenever it deems convenient with little or no apparent cost. (Investors believe this now and, worse still, the government believes it as well. We are probably doomed to a lasting legacy of government tampering with financial markets and the economy, which is likely to create the mother of all moral hazards. The government is blissfully unaware of the wisdom of Friedrich Hayek: "The curious task of economics is to demonstrate to men how little they really know about what they imagine they can design.")

10. Can one person successfully play different roles that require different, and often competing, perspectives?

No, according to research by Max Bazerman, author of the best book on decision making I've ever read: *Judgment in Managerial Decision Making*.

Contrary to F. Scott Fitzgerald's famous quote, "the test of a first-rate intelligence is the ability to hold two opposed ideas in the mind at the same time, and still retain the ability to function," evidence suggests that even the most intelligent find it difficult to sustain opposing beliefs without the two influencing each other.

Why?

One reason is a bias from incentives. Another is bounded awareness. The auditor who desperately wants to retain a client's business may have trouble adopting the perspective of a dispassionate referee when it comes time to prepare a formal evaluation of the client's accounting practices.

* * * * *

In many situations, professionals are called upon to play dual roles that require different perspectives. For example, attorneys embroiled in pretrial negotiations may exaggerate their chances of winning in court to extract concessions from the other side. But when it comes time to advise the client on whether to accept a settlement offer, the client needs objective advice.

Professors, likewise, have to evaluate the performance of graduate students and provide them with both encouragement and criticism. But public criticism is less helpful when faculty serve as their students' advocates in the job market. And, although auditors have a legal responsibility to judge the accuracy of their clients' financial accounting, the way to win a client's business is not by stressing one's legal obligation to independence, but by emphasizing the helpfulness and accommodation one can provide.

Are these dual roles psychologically feasible?; that is, can one person successfully play different roles that require different, and often competing, perspectives? No.

Abstract

This paper explores the psychology of conflict of interest by investigating how conflicting interests affect both public statements and private judgments. The results suggest that judgments are easily influenced by affiliation with interested partisans, and that this influence extends to judgments made with clear incentives for objectivity. The consistency we observe between public and private judgments indicates that participants believed their biased assessments. Our results suggest that the psychology of conflict of interest is at odds with the way economists and policy makers routinely think about the problem. We conclude by exploring implications of this finding for professional conduct and public policy.

11. Hiring and the Mismatch Problem

“We want to cling to these incredibly outdated and simplistic measures of ability.”

— Malcolm Gladwell

Hiring is difficult and we tend to fall back on antiquated tools that give us a number (something, anything) to help us evaluate potential employees. This creates what Malcolm Gladwell calls “mismatch problems” — when the criteria for evaluating job candidates is out of step with the reality of the job demands.

Of course, we never think our criteria is out of step.

The mismatch problem shows itself all over the sports world. Although the study below was released in 2008, Gladwell has long illustrated the point that sports combines (events professional sports leagues hold for scouts to evaluate potential draftees based on a battery of ‘tests’) don’t work.

Gladwell’s results echo what Michael Lewis talks about in Moneyball: Combines are a poor predictor of determining ultimate success. Mismatch problems transcend the sports world. Teachers are another example. While we tend to evaluate teachers based on high test scores, the number of degrees and other credentials, that makes little difference in how well people actually teach.

Some companies, like Google, are trying to attack this problem. Google tried to find correlations between ‘great’ existing employees. When they find correlations, say like most people who score 9/10 on performance reviews, own a dog, they try to work that into their hiring. By constantly evaluating the actual results of their hiring, rethinking how they hire, and removing questions and evaluations that show no bearing on actual performance they are taking steps to try to eliminate the mismatch problem.

Google also knows hiring lacks certainty; they are just trying to continuously improve and refine the process. Interestingly, very few workforces are so evidence-based. Rather the argument becomes hiring works because it has always ‘worked’...

So why do mismatch problems exist?

Because we desire certainty. We want to impose certainty on something that is not, by nature, certain. The increase in complexity doesn’t help either.

Charlie Munger”“The craving for that physics-style precision does nothing but get you in terrible trouble.

12. Youngme Moon: On Business Competition and Escaping the Competitive Herd

There are many ways companies compete with one another. Unfortunately, a lot of those ways seem like nothing more than an expensive route to commoditization.

Companies are relentless in their pursuit of finding their weaknesses. They hire consultants, create branding maps, and solicit customer feedback. In our hyper-competitive world, this feedback tells us what we're missing—our weaknesses.

Companies, like people, fall into the habit of thinking the way to be better is to become more like everyone else.

- Jane's company just introduced a new line of green worms? We need green worms too preferably caffeine enhanced green worms.
- Bob decided to offer a new service? We need a new service too!
- When you ask your customers what they want they respond with what you're missing.
- When consultants compare your products to others they tell you what the competition offers that you don't.

"A funny thing happens when you begin to capture competitive differences on paper", says Harvard Professor Youngme Moon in her book Different: Escaping the Competitive Herd, "there is a natural inclination for folks in the competitive set to focus on eliminating differences rather than accentuating them."

Eliminating Differences

Our brains have been wired since birth to eliminate our differences.

We've all received school report cards. If you're like most people, at some point or another, you discovered you were below the class average in something. We all knew our parents would pick up on that weakness right away.

I cringed before coming home if I was even a hair below average in anything. After a mother saw that report card, it didn't matter how awesome you were in physics and math. The only thing that mattered was the fact that you were below average in art.

If your mother was like my mother, you wouldn't hear the end of it until you were once again average in art.

As adults, the only thing that has changed is who gives the report card.

Managers across the country hand out performance reviews that highlight your strengths and weaknesses. Of course, your boss wants you to address those weaknesses. He wants you to be more like everyone else. And since keeping your job is a pretty big incentive, you eagerly put your head down and do what you've done your whole life: rather than accentuate the differences you address your weaknesses and, in the process, become more average and indistinguishable from everyone else.

In the process, you move increasingly towards becoming a commodity.

Competition

It's like we're back in school all over; competitors and customers are telling us what we don't have—where we're below average. Only now this isn't grade school. The stakes are higher. It's winner take all and our competitive spirits take over. Except, increasingly, there is no winner.

Consumers can't tell company Y from Company X. Shelves in grocery stores are full of products that are all essentially the same. Companies think that the way to improve their laundry detergent is simply to add a new, previously unknown, fragrance. Being more of the same is, according to Moon, making brand loyalty harder to find.

Of course, if consumers pay close attention, these products have minute differences. But most of these differences are essentially meaningless.

Competing by eliminating our differences seems like nothing more than an expensive route to commoditization.

- When one airline introduced frequent flier miles the rest soon followed and the industry offerings were, once again, almost indistinguishable.
- When the Westin started offering the Heavenly Bed as a way to differentiate itself from the competition, almost immediately most other hotels at the same price point upgraded their mattresses too. The only problem was that room rates didn't increase to make up for the new investment. When everyone can offer essentially the same bed it becomes hard to differentiate yourself and raise prices in the process.

Ultimately, all of the advantages flow to the customers (and the mattress companies). According to Moon, "The more generous the baseline value proposition becomes within the category, the easier it becomes for consumers to become indifferent and the more expensive it becomes for businesses to compete." Investing in differentiation without the ability to increase prices or market share only reduces returns.

In the race to become more like everyone else, companies often don't think through the whole problem.

They "don't do the second step of the analysis which is to determine how much is going stay home and how much is just going to flow through to the customer," says longtime investor Charlie Munger.

I've never seen a single projection incorporating that second step in my life. And I see them all the time. Rather, they always read: This capital outlay will save you so much money that it will pay for itself in three years. So you keep buying things that will pay for themselves in three years. And after 20 years of doing it, somehow you've earned a return of only about 4% per annum.

If this sounds vaguely familiar it should. It's a variation of the prisoners' dilemma; the best choice for all companies is not the best choice for each individual company.

I'm not saying that all competition based on product augmentation (either through new sub-categories or new features) is a flawed strategy. Under the right circumstances, some of these investments can, and will, pan out. I am saying that if your business is pursuing one of these strategies as a means of differentiating yourself from competition, you need to critically think through this strategy.

13. Solution By Recognition

In his autobiography, legendary scientist Herber Simon attempts to explain the difference between experienced decision-makers and novices.

What is it that the expert has that the novice lacks? Simon argues the answer is not judgment or intuition but rather a repository of possible actions to take in a given circumstance.

One can train a man so that he has at his disposal a list or repertoire of the possible actions that could be taken under the circumstances...A person who is new at the game does not have immediately at his disposal a set of possible actions to consider, but has to construct them on the spot – a time- consuming and difficult mental task.

The decision maker of experience has at his disposal a checklist of things to watch out for before finally accepting a decision. A large part of the difference between the experienced decision maker and the novice in these situations is not any particular intangible like “judgment” or “intuition.” If one could open the lid, so to speak, and see what was in the head of the experienced decision-maker, one would find that he had at his disposal repertoires of possible actions; that he had checklists of things to think about before he acted; and that he had mechanisms in his mind to evoke these, and bring these to his conscious attention when the situations for decisions arose.

Most of what we do is to get people ready to act in situations of encounter consists of drilling in these lists into them sufficiently deeply so that they will be evoked quickly at the time of the decision.

Simon points out three advantages of the experts: (1) a repository of actions, (2) A checklist of things to think about before acting, and (3) making the process conscious. Let's briefly explore these three.

A repository of actions — If you're just starting out, copying others will quickly get you average results. You need not limit yourself to copying the living. You can build a repository of possible actions from the greats of history as well: Rockefeller, Mellon, Carnegie, etc.

A checklist of things to think about — Consider all of your decisions through a two-step process. First, what are the variables that govern the situation? For this, you can use your specific understanding and general knowledge of the world. Second, consider how you trick yourself.

Making the process conscious — It's easy to use your intuition. It takes a lot of work and effort to use a repeatable process for decisions that you can use to look for mistakes.

In the end, the novice spends a lot of time considering a possible course of action, whereas the expert spends much of their time thinking about where a particular action leaves him. The novice spends time searching for what they could do? The expert, already filled with a repository of possible actions, asks what happens if they take a particular action.

14. Choice Under Uncertainty

We use heuristics – rules of thumb – to make judgments. These can lead to certain predictable biases.

These can lead to certain predictable biases. For instance, we classify situations based on their representativeness. We judge the frequency of events based on the availability of examples in our minds. We interpret problems based on how they are framed. These heuristics have important implications for individuals and society as a whole.

Here are some common heuristics and how they can lead us astray.

Insensitivity to Base Rates

In statistics, a base rate is how probable something is in the absence of other information. When we receive information about the base rate of something, followed by some additional information, we tend to ignore the former. We disregard the base rate in favor of irrelevant information. For instance, if you tell study participants that 70% of the people in a room are lawyers and the rest are engineers, then ask them to guess the profession of a random, simply described person. People will guess they are a lawyer only half of the time, even though the probability is 70%.

Insensitivity to Sample Size

A sample size is the number of things observed in a statistical study, such as the number of people who answer a survey.

We often misjudge probabilities when we fail to consider the influence of sample size. For example, if you ask people to estimate the probability that more than 60% of the babies born in a hospital during a given week are male, people do not adjust their estimates based on the total number of babies. This is despite the fact that a percentage above 50% is more likely in smaller samples due to randomness.

Availability

The 'availability' of something refers to how easily it comes to mind. We tend to think things which are more available are more common than those which are harder to recall. In one experiment, subjects heard a list of names of both male and female people. They were then asked to judge whether there were more men or women named. In one list, the men were more famous, in the other the women were. Participants judged that there were more men when the names were famous and vice versa. The names were more available in their minds.

Framing and Loss Aversion

The way in which an uncertain possibility is presented may have a substantial effect on how people respond to it. When asked whether they would choose surgery in a hypothetical medical emergency, many more people said that they would when the chance of survival was given as 80 percent than when the chance of death was given as 20 percent.

15. Ethical Breakdowns: Why Good People often Let Bad Things Happen

When Charlie Munger recommended reading Max Bazerman's *Judgment in Managerial Decision Making* I had never heard of the HBS professor. A lot of reading later and I'm a huge fan.

In the HBR article below Bazerman covers some of the ground from his new book *Blind Spots* (see my [notes](#)).

These days, many of us are instructed to make decisions from a business perspective (thereby reducing or eliminating the ethical implications of our decisions). The Ford Pinto example below is very telling:

Consider an infamous case that, when it broke, had all the earmarks of conscious top-down corruption. The Ford Pinto, a compact car produced during the 1970s, became notorious for its tendency in rear-end collisions to leak fuel and explode into flames. More than two dozen people were killed or injured in Pinto fires before the company issued a recall to correct the problem. Scrutiny of the decision process behind the model's launch revealed that under intense competition from Volkswagen and other small-car manufacturers, Ford had rushed the Pinto into production. Engineers had discovered the potential danger of ruptured fuel tanks in preproduction crash tests, but the assembly line was ready to go, and the company's leaders decided to proceed. Many saw the decision as evidence of the callousness, greed, and mendacity of Ford's leaders—in short, their deep unethicity.

But looking at their decision through a modern lens—one that takes into account a growing understanding of how cognitive biases distort ethical decision making—we come to a different conclusion. We suspect that few if any of the executives involved in the Pinto decision believed that they were making an unethical choice. Why? Apparently because they thought of it as purely a business decision rather than an ethical one.

Taking an approach heralded as rational in most business school curricula, they conducted a formal cost-benefit analysis—putting dollar amounts on a redesign, potential lawsuits, and even lives—and determined that it would be cheaper to pay off lawsuits than to make the repair. That methodical process colored how they viewed and made their choice. The moral dimension was not part of the equation. Such “ethical fading,” a phenomenon first described by Ann Tenbrunsel and her colleague David Messick, takes ethics out of consideration and even increases unconscious unethical behavior.

16. The Art and Science of High-Stakes Decisions

How can anyone make rational decisions in a world where knowledge is limited, time is pressing, and deep thought is often unattainable?

Some decisions are more difficult than others. Yet we're often forced to make all of our decisions the way we make easy ones: on autopilot.

One particular difficulty we have is with making decisions that help us avoid threats which are low probability, but high stakes. We are least prepared to make the decisions that matter the most.

Sure we can pick the right brand of peanut butter with ease. But life offers few opportunities to prepare for the type of decisions which could have catastrophic consequences. The kinds of decisions which could wipe us out if we mess up.

Shortly after 9/11 some well-known academics got together to discuss¹ how people make choices involving low and ambiguous probability of a high-stakes loss.

High-stakes decisions involve two distinctive properties:

- 1) existence of a possible large loss (financial or emotional) and
- 2) the costs to reverse decisions once made are high.

More importantly, these professors wanted to determine if prescriptive guidelines for improving decision-making process could be created in an effort to help make better decisions.

Whether we're buying something at the grocery store or making a decision to purchase earthquake insurance, we operate in the same way. The possibility of catastrophic outcomes does little to reduce our reliance on heuristics (rules of thumb.) These serve us well most of the time, when the cost of an error is low. However, they can often be a poor technique for high-stakes decisions.

In order to make better high-stakes decisions, we need a better understanding of why we generally make poor decisions.

Here are several causes.

Poor understanding of probability.

Several studies show that people either utilize probability information insufficiently when it is made available to them or ignore it all together. In one study, 78% of subjects failed to seek out probability information when evaluating between several risky managerial decisions.

In the context of high-stakes decisions, the probability of an event causing loss may seem sufficiently low that organizations and individuals consider them not worth worry about. In doing so, they effectively treat the probability of something as zero or close to it.

An excessive focus on short time horizons.

Many high-stakes decisions are not obvious to the decision-maker. In part, this is because people tend to focus on the immediate consequences and not the long-term consequences.

A CEO near retirement has incentives to skimp on insurance to report slightly higher profits before leaving (shareholders are unaware of the increased risk and appreciate the increased profits). Governments tend to under-invest in less visible things like infrastructure because they have short election cycles. The long-term consequences of short-term thinking can be disastrous.

The focus on short-term decision making is one of the most widely-documented failings of human decision making. People have difficulty considering the future consequences of current actions over long periods of time. Garrett Hardin, the author of Filters against Folly, suggests we look at things through three filters (literacy, numeracy, and ecolacy). In ecolacy, the key question is "and then what?" And then what helps us avoid a focus solely on the short-term.

Excessive attention to what's available.

Decisions requiring difficult trade-offs between attributes or entailing ambiguity as to what a right answer looks like often leads people to resolve choices by focusing on the information most easily brought to mind. Sometimes things can be difficult to bring to mind. Constant exposure to low-risk events without realization leads to us being less concerned than we probably would warrant (it makes these events less available) and “proves” our past decisions to ignore low-risk events were right.

People refuse to buy flood insurance even when it is heavily subsidized and priced far below an actuarially fair value. Kunreuther et. al. (1993) suggests underreaction to threats of flooding may arise from *“the inability of individuals to conceptualize floods that have never occurred... Men on flood plains appear to be very much prisoners of their experience... Recently experienced floods appear to set an upward bound to the size of loss with which managers believe they ought to be concerned.”* Paradoxically, we feel more secure even as the “risk” may have increased.

Distortions under stress.

Most high-stakes decisions will be made under perceived (or real) stress. A large number of empirical studies find that stress focuses decision-makers on a selective set of cues when evaluating options and leads to greater reliance on simplifying heuristics. When we’re stressed, we’re less likely to think things through.

Over-reliance on social norms.

Most individuals have little experience with high-stakes decisions and are highly uncertain about how to resolve them (procedural uncertainty). In such cases—and combined with stress—the natural course of action is to mimic the behavior of others or follow established social norms. This is based on the psychological desire to fail conventionally.

The tendency to prefer the status-quo.

What happens when people are presented with difficult choices and no obvious right answer? We tend to prefer making no decision at all, we choose the norm.

In high-stakes decisions many options are better than the status-quo and we must make trade-offs. Yet, when faced with decisions that involve life-and-death trade-offs, people frequently remark “I’d rather not think about it.”

Failures to learn.

Although individuals and organizations are eager to derive intelligence from experience, the inferences stemming from that eagerness are often misguided. The problems lie partly in errors in how people think, but even more so in properties of experience that confound learning from it. Experience may possibly be the best teacher, but it is not a particularly good teacher.

As an illustration, one study finds that participants in an earthquake simulation tended to over-invest in mitigation that was normatively ineffective but under-invest when it is normatively effective. The reason was a misinterpretation of feedback; when mitigation was ineffective, respondents attributed the persistence of damage to the fact that they had not invested enough. by contract, when it was effective, they attributed the absence of damage to a belief that earthquakes posted limited damage risk.

Gresham’s Law of Decision making.

Over time, bad decisions will tend to drive out good decisions in an organization.

Improving.

What can you do to improve your decision-making?

A few things:

- 1) learn more about judgment and decision making;
- 2) encourage decision makers to see events through alternative frames, such as gains versus losses and changes in the status-quo;
- 3) adjust the time frame of decisions—while the probability of an earthquake at your plant may be 1/100 in any given year, the probability over the 25 year life of the plant will be 1/5; and

4) read Farnam Street!

17. Problem Solving Tools

When you're faced with problems, do you have the right tools to handle them? I didn't use to. My approach consisted mostly of guesswork and dumb luck. It worked sometimes. But I wanted to improve my ability to make good decisions. So I bought a lot of books on the topic, deciding to invest my time in finding tools that would improve my ability to solve problems.

The book with the most problem solving tools is one that I didn't think I'd enjoy at all: Problem Solving 101 by Ken Wantanabe.

This book offered a simple way to deal with problems that I can still recall today: (1) understand the current situation; (2) identify the root cause of the problem; (3) develop an effective action plan; and (4) execute until the problem is solved.

While simple—and remarkably effective—the process is not easy to execute.

If you've ever found yourself in the middle of a problem solving meeting you know that our bias towards action causes us to want to skip steps 1 and 2. We're prone to action. We want to shoot first and ask questions later.

This bias makes the simple four step approach above almost painful. If we think we understand the problem our minds naturally see steps 1 and 2 as a waste. The next time you find yourself in an unfortunate problem solving meeting ask yourself a few questions – are we addressing a problem or a symptom. If you're addressing a problem, does everyone in the room agree on the problem? How will we know we've solved the problem? Think about how doctors diagnose patients.

When you visit a doctor they first ask you questions about your symptoms and then take your temperature. They might run a blood test or two. Maybe order an X-Ray. They collect information that can be used to identify the root cause of your illness. After they've determined, and hopefully confirmed, a diagnosis they decide what to prescribe. While the process isn't the most efficient, it leads to good outcomes more often than not.

If you want to learn to solve problems better, you should buy problem solving 101. If you're really motivated, check out judgment and managerial decision making too. Exercising your brain is time well spent.

18. Albert Bernstein on the Dinosaur Brain and How To Make Bad Decisions

I enjoyed reading Dinosaur Brains: Dealing with All Those Impossible People at Work by Albert Bernstein.

Near the end of the book, Bernstein playfully illuminates how too many decisions get made.

1. *Take an idea from some authority figure, maybe your boss, or an author;*
2. *Tell everyone this idea is the basis for all the change you're going to make;*
3. *Do things the way you've always done them;*
4. *If something changes, take credit for it. If something bad happens, point out that this just goes to show that the old way of doing things was better.*

Sound familiar? It should.

Another approach, let's call it the more rational approach, might look something like:

1. Understand the problem, or set a goal;
2. Establish criteria (how will you know the problem is solved or you've reached your goal);
3. Generate alternatives;
4. Measure alternatives versus criteria and try a few of them;
5. Evaluate;
6. Choose the best solution.

This approach probably won't get you promoted, but it will *increase the odds* of making better decisions.

19. Suppressing Volatility: Making the World Less Predictable and More Dangerous

Nassim Taleb's article, The Black Swan of Cario, ([PDF](#)) on suppressing volatility is worth a read.

It's the ultimate example of iatrogenics by the fragilista.

Here are my notes.

- Complex systems that have artificially suppressed volatility tend to become extremely fragile, while at the same time exhibiting not visible risks.
- Seeking to restrict variability seems to be good policy (who does not prefer stability to chaos?), so it is with very good intentions that policymakers unwittingly increase the risk of major blowups.
- Because policymakers believed it was better to do something than to do nothing, they felt obligated to heal the economy rather than wait and see if it healed on its own.
- Those who seek to prevent volatility on the grounds that any and all bumps in the road must be avoided paradoxically increase the probability that a tail risk will cause a major explosion. Consider as a thought experiment a man placed in artificially sterilized environment for a decade and then invited to take a ride on a crowded subway; he would be expected to die quickly.
- But although these controls might work in some rare situations, in the long-term effect of any such system is an eventual and extremely costly blowup whose cleanup costs can far exceed the benefits accrued.
- ... Government interventions are laden with unintended—and unforeseen—consequences, particularly in complex systems, so humans must work with nature by tolerating systems that absorb human imperfections rather than seek to change them.
- Although it is morally satisfying, the film (inside job) naively overlooks the fact that humans have always been dishonest and regulators have always been behind the curve.
- Humans must try to resist the illusion of control: just as foreign policy should be intelligence-proof (it should minimize its reliance on the competence of information-gathering organizations and the predictions of “experts” in what are inherently unpredictable domains), the economy should be regulator-proof, given that some regulations simply make the system itself more fragile.
- The “turkey problem” occurs when a naive analysis of stability is derived from the absence of past variations.
- Imagine someone who keep adding sand to a sand pile without any visible consequence, until suddenly the entire pile crumbles. It would be foolish to blame the collapse on the last grain of sand rather than the structure of the pile, but that is what people do consistently, and that is the policy error.
- As with a crumbling sand pile, it would be foolish to attribute the collapse of a fragile bridge to the last truck that crossed it, and even more foolish to try to predict in advance which truck might bring it down.
- Obama's mistake illustrates the illusion of local causal chains—that is, confusing catalysts for causes and assuming that one can know which catalyst will produce which effect.
- Governments are wasting billions of dollars on attempting to predict events that are produced by interdependent systems and are therefore not statistically understandable at the individual level.

- Most explanations being offered for the current turmoil in the Middle East follow the “catalysts as causes” confusion. The riots in Tunisia and Egypt were initially attributed to rising commodity prices, not to stifling and unpopular dictatorships.
- Again, the focus is wrong even if the logic is comforting. It is the system and its fragility, not events, that must be studied—what physicists call “percolation theory,” in which the properties of the terrain are studied rather than those of a single element of the terrain.
- Humans fear randomness—a healthy ancestral trait inherited from a different environment. Whereas in the past, which was a more linear world, this trait enhanced, fitness and increased changes of survival, it can have the reverse effect in today’s complex world, making volatility take the shape of nasty Black Swans hiding behind deceptive periods of “great moderation.”
- But alongside the “catalysts as causes” confusion sit two mental biases: the illusion of control and the action bias (the illusion that doing something is always better than doing nothing.) This leads to the desire to impose man-made solutions. Greenspan’s actions were harmful, but it would have been hard to justify inaction in a democracy where the incentive is to always promise a better outcome than the other guy, regardless of the actual delayed cost.
- As Seneca wrote in De clementia, “repeated punishment, while it crushes the hatred of a few, stirs the hatred of all ... just as trees that have been trimmed throw out again countless branches.”
- The Romans were wise enough to know that only a free man under Roman law could be trusted to engage in a contract; by extension, only a free people can be trusted to abide by a treaty.
- As Jean-Jacques Rousseau put it, “A little bit of agitation gives motivation to the soul, and what really makes the species prosper is not peace so much as freedom.” With freedom comes some unpredictable fluctuation. This is one of life’s packages: there is no freedom without noise—and no stability without volatility.

20. Just for you: How Scarcity Factors Into Decisions

Rather than invest the time and effort necessary to ponder the pluses and minuses of most decisions, we tend to rely on quick heuristics to make most decisions. These rules of thumb help us save cognitive processing and navigate a world full of choices. Our tendency to make near-automatic decisions exposes us to exploitation by individuals who understand how heuristics work.

In the study below the authors were interested in what role the scarcity principle—the notion that the less available an opportunity appears, the more valuable it becomes—plays in decision compliance and heuristics.

Previously, there were two main ways that we thought scarcity played a role in compliance situations.

First, something, a product for example, can be described as being in short supply (or a limited edition. This is why sales often say “while supplies last” which leaves the reader with a slight nudge to purchase right now before missing out. Second, scarcity affects compliance when an opportunity is available for a limited time (e.g., “This weekend only.”) While these principles don’t ensure that someone will purchase a product, they do increase the odds of a purchase.

The authors wanted to test another way that scarcity might factor into our decisions. They hypothesized that we naturally rely on a rule of thumb (heuristic) that says one should take advantage of a unique opportunity. Specifically, “the rule says that we should take advantage of opportunities that few others have access to. For example, if I believe I can purchase tickets to a play at a low price that is unavailable to most people, I am more likely to buy the tickets than if I believe many people have access to this same price.”

We’ve all seen examples of this type of marketing already through “friends and family” and “not available to the public” events. But do they work?

The authors certainly think so:

individuals are more likely to comply with a request when they believe the request represents a unique opportunity not available to most people. The effect appears to operate independently of a limited supply effect and is not the result of a perceived need to help the requester. Moreover, the effect is found even when the opportunity is determined purely by chance, suggesting that individuals are not responding to a sense that they have somehow earned the opportunity. Rather, the unique opportunity effect appears to be the result of heuristic processing, i.e., people relying on a rule of thumb that says they should grab an opportunity available to few others.

Source: Burger, J. M. & Caldwell, D.C., When opportunity knocks: The effect of a perceived unique opportunity on compliance. *Group Processes and Intergroup Relations*

Abstract:

Four studies examined the effect of a perceived unique opportunity on compliance. In all four studies, participants who believed they had an opportunity available to few others were more likely to agree with a request than participants who believed the opportunity was widely available or participants who received no opportunity information. We attribute the effect to a widely held heuristic that one should take advantage of unique opportunities. Study results demonstrated that people respond to a perceived unique opportunity even when supplies are not limited and when the opportunity is the result of pure chance. The results of a mediation analysis supported the interpretation that the perceived uniqueness of the opportunity underlies the effect.

21. A Simple Checklist to Improve Decisions

We owe thanks to the publishing industry. Their ability to take a concept and fill an entire category with a shotgun approach is the reason that more people are talking about biases. Unfortunately, talk alone will not eliminate them but it is possible to take steps to counteract them. Reducing biases can make a huge difference in the quality of any decision and it is easier than you think.

In a recent article for Harvard Business Review, Daniel Kahneman (and others) describe a simple way to detect bias and minimize its effects in the most common type of decisions people make: determining whether to accept, reject, or pass on a recommendation. The Munger two-step process for making decisions is a more complete framework, but Kahneman's approach is a good way to help reduce biases in our decision-making. If you're short on time here is a simple checklist that will get you started on the path towards improving your decisions:

Preliminary Questions: Ask yourself

1. Check for Self-interested Biases

- Is there any reason to suspect the team making the recommendation of errors motivated by self-interest?
- Review the proposal with extra care, especially for overoptimism.

2. Check for the Affect Heuristic

- Has the team fallen in love with its proposal?
- Rigorously apply all the quality controls on the checklist.

3. Check for Groupthink

- Were there dissenting opinions within the team?
- Were they explored adequately?
- Solicit dissenting views, discreetly if necessary.
- Challenge Questions: Ask the recommenders

4. Check for Saliency Bias

- Could the diagnosis be overly influenced by an analogy to a memorable success?
- Ask for more analogies, and rigorously analyze their similarity to the current situation.

5. Check for Confirmation Bias

- Are credible alternatives included along with the recommendation?
- Request additional options.

6. Check for Availability Bias

- If you had to make this decision again in a year's time, what information would you want, and can you get more of it now?
- Use checklists of the data needed for each kind of decision.

7. Check for Anchoring Bias

- Do you know where the numbers came from? Can there be
- ...unsubstantiated numbers?
- ...extrapolation from history?
- ...a motivation to use a certain anchor?
- Reanchor with figures generated by other models or benchmarks, and request new analysis.

8. Check for Halo Effect

- Is the team assuming that a person, organization, or approach that is successful in one area will be just as successful in another?
- Eliminate false inferences, and ask the team to seek additional comparable examples.

9. Check for Sunk-Cost Fallacy, Endowment Effect

- Are the recommenders overly attached to a history of past decisions?

- Consider the issue as if you were a new CEO.
 - Evaluation Questions: Ask about the proposal
10. Check for Overconfidence, Planning Fallacy, Optimistic Biases, Competitor Neglect
- Is the base case overly optimistic?
 - Have the team build a case taking an outside view; use war games.
11. Check for Disaster Neglect
- Is the worst case bad enough?
 - Have the team conduct a premortem: Imagine that the worst has happened, and develop a story about the causes.
12. Check for Loss Aversion
- Is the recommending team overly cautious?
 - Realign incentives to share responsibility for the risk or to remove risk.

22. Promoting People In Organizations

In their 1978 paper Performance Sampling in Social Matches, researchers March and March discussed the implications of performance sampling for understanding careers in organizations. They came to some interesting conclusions with implications for those of us working in organizations.

Considerable evidence exists documenting that individuals confronted with problems requiring the estimation of proportions act as though sample size were substantially irrelevant to the reliability of their estimates. We do this in hiring all the time. Yet we know that sample size matters.

On how this cognitive bias affects hiring, March and March offer some good insights including the false record effect, the hero effect, the disappointment affect.

False Record Effect

A group of managers of identical (moderate) ability will show considerable variation in their performance records in the short run. Some will be found at one end of the distribution and will be viewed as outstanding; others will be at the other end and will be viewed as ineffective. The longer a manager stays in a job, the less the probable difference between the observed record of performance and actual ability. Time on the job increased the expected sample of observations, reduced expected sampling error, and thus reduced the chance that the manager (of moderate ability) will either be promoted or exit.

Hero Effect

Within a group of managers of varying abilities, the faster the rate of promotion, the less likely it is to be justified. Performance records are produced by a combination of underlying ability and sampling variation. Managers who have good records are more likely to have high ability than managers who have poor records, but the reliability of the differentiation is small when records are short.

Disappointment Effect

On the average, new managers will be a disappointment. The performance records by which managers are evaluated are subject to sampling error. Since a manager is promoted to a new job on the basis of a good previous record, the proportion of promoted managers whose past records are better than their abilities will be greater than the proportion whose past records are poorer. As a result, on the average, managers will do less well in their new jobs than they did in their old ones, and observers will come to believe that higher level jobs are more difficult than lower level ones, even if they are not.

...The present results reinforce the idea that indistinguishability among managers is a joint property of the individuals being evaluated and the process by which they are evaluated. Performance sampling models show how careers may be the consequences of erroneous interpretations of variations in performance produced by equivalent managers. But they also indicate that the same pattern of careers could be the consequence of unreliable evaluation of managers who do, in fact, differ, or of managers who do, in fact, learn over the course of their experience.

But hold on a second before you stop promoting new managers (who, by definition, have a limited sample size).

I'm not sure that sample size alone is the right way to think about this.

Consider two people: Manager A and Manager B who are up for promotion. Manager A has 10 years of experience and is an "all-star" (that is great performance with little variation in observations). Manager B, on the other hand, has only 5 years of experience but has shown a lot of variance in performance.

If you had to hire someone you'd likely pick A. But it's important not to misinterpret the results of March and March and dig a little deeper.

What if we add one more variable to our two managers.

Manager A's job has been "easy" whereas Manager B took a very "tough" assignment.

With this in mind, it seems reasonable to conclude that Manager B's variance in performance could be explained by the difficulty of their task. This could also explain the lack of variance in Manager A's performance.

Some jobs are tougher than others.

If you don't factor in degree-of-difficulty you're missing something big and sending a message to your workforce that discourages people from taking difficult assignments.

The importance of measuring performance over a meaningful sample size is the key to distinguishing between luck and skill. When in doubt go with the person that's excelled with more variance in difficulty.

23. Intervention Bias: When to Step in and When To Leave Things Alone

When we want to improve a situation, our first instinct is often to change something. Try something new. Make adjustments. Anything other than what we're already doing. But this approach is frequently misguided. Sometimes doing nothing at all or removing inputs is the better approach.

Nassim Taleb, author of many books—The Black Swan, Fooled By Randomness, and The Bed of Procrustes—also wrote a book on fragility called Antifragile (antifragile defined).

One of the core ideas of Antifragile is around our tendency to intervene in situations *regardless* of whether that benefit is a net positive. There is a term for this, *iatrogenics*. Why do we do this? I can think of three good reasons: 1) we struggle to think in systems, 2) we believe that systems would benefit from our intervention and guidance, and 3) we believe that we know how to fix things to make them better.

The first reason is that we are unable to think in terms of second, third, and nth order consequences. More importantly, we are unaware that we need to. The second reason is that we see systems operating and see a flaw in the system that we could do better. Usually, it's minor. This combines with the third reason, which is we think we are the very person that needs to fix the system.

Here's Taleb expanding on this idea:

There is a mental defect psychologists call illusion of control that lead to a default to action rather than inaction, even when the benefits of inaction might be greater than those of action. So the intervention bias" (do something seems better than doing nothing, which is fine except that there are cases in which it gets us in trouble). The illusion of control was meant to show how "irrational" (according to some norm of behavior) we humans can be by giving ourselves the illusion to manage the uncontrollable around us: for instance gamblers cannot resist the pressure to do something in order to improve the outcome, such as throw the die with violence when they need a high number, or throw it softly in order to get a low one. Traders cannot resist wearing the same "lucky" shirt (often unwashed) to improve their day and feel they need to find similar way to take control of their destiny. This mental bias leads to all manner of patently "irrational" actions such as belief in paranormal, alternative medicine and many such actions often put under the umbrella magical thinking. Now the irony is that while this bias was devised to expose patently nonscientific fields, it largely affects many things you learn in college, particularly in social science. Many matters we deem scientific are just the fruit of that very illusion of control masquerading as science with, of course, actions to "improve" mankind.

Why is the scientific illusion of control worse than that of the pedestrian version? Because, tout simplement, these gamblers superstitions are benign, not much worse than doing nothing—they may be even beneficial in hidden ways, and in the right environment. But a doctor tinkering with your system or an army playing with a complex system with opaque causal links, say by invading Iraq, giving chemicals to kids and threatening their brain balance, or intervening in the environment, is far worse than nothing.

This variant of the illusion of control leads to the denigration of acts of omission (not doing something, letting things run their own course, leaving nature or the human body alone) as compared to doing something (such as operating on a patient or prescribing medication). This, we will see is the reason medicine used, until recent history, to kill more patients than it saved (and did not even get close to realizing it), and economists of the sophisticated equation-carrying variety, I will hope to convince you, have been particularly harmful to the economic health of societies—central bankers, and finance ministers, by tinkering with economic life, have caused massive instability.

24. Why is it so Hard to Kill a Cockroach with your Shoe?

The Cockroach Papers by Richard Schwied is an interesting book if you are looking to learn more about biology or evolution. Cockroaches are built for survival no matter what the world throws at them. Their ability to adapt is just amazing.

Here are some of my notes from the book.

Food and Water

German cockroaches, *Blattella germanica*, the most common domestic roach in the United States, have been observed to live 45 days without food, and more than two weeks with neither food nor water.

Cockroaches will eat almost anything including glue, feces, hair, decayed leaves, paper, leather, banana skins, other cockroaches, and dead or alive humans. They will not, however, eat cucumbers. They are particularly fond of dried milk around a baby's mouth. The roaches are not confined to any particular environment and live in a tremendous variety of places, from underneath woodpiles in Alaska to high in the jungle canopy in the tropics of Costa Rica. They are even found in the caves of Borneo and under the thorn bushes in arid stretches of Kenya. Wherever they live, they are masters at surviving. They are, Schwied writes, "undeniably one of the pinnacles of evolution on this planet."

Why is it so hard to kill a cockroach with your shoe?

Schweid observes that "when a cockroach feels a breeze stirring the hairs on its cerci, it does not wait around to see what is going to happen next, but leaves off whatever it is doing and goes immediately into escape mode in something remarkably close to instantaneous fashion." Studies show that a cockroach can respond in about 1/20th of a second, so "by the time a light comes on and human sight can register it, much less react by reaching for and hoisting something with which to squash it, a roach is already locomoting towards safety."

Blood

Cockroach blood is a pigments, clear substance circulating through the interior of its body, and what usually spurts out of a roach when its hard, , outer shell—its exoskeleton—is penetrated or squashed is a cream-colored substance resembling nothing so much as pus or smegma.

Brains

Cockroaches have two brains—one inside their skulls, and a second, more primitive brain that is back near their abdomen.

Copulation

Schweid says "Pheromones, chemical signals of sexual readiness, operate between a male and female cockroach to initiate courtship and copulation. A sexually receptive female assumes a posture with her abdomen lowered and her wings raised and gives off a pheromone that attracts males." If he finds a virgin female, a male cockroach after some antenna rubbing foreplay will turn away from the female and raise his wings, "an invitation to her to mount." Copulation frequently lasts an hour. After sex, female cockroaches store the sperm and use them as needed. The sperm may last her a lifetime.

"The evolutionary strategy employed by cockroaches to reproduce is considerably more efficient than that employed by humans." Oddly, there are certain species of cockroaches that can, at least for a generation or two, reproduce without any sperm. Schweid says "the females unfertilized eggs will develop and hatch—always producing new females."

Partying

Betty Faber, the former staff entomologist for the New York Natural History Museum, says "Females go to bed—by which I mean disappear back to the harborage—at night earlier than males."

Socialness

Schweid writes, "cockroaches, while not social insects in the entomological sense of bees

or ants with clearly assigned tasks that benefit the whole community, do clearly take pleasure in the company of other roaches, and the aggression pheromones draw them together, eliciting their effects regardless of the sex or age.” Cockroaches reared singly develop more slowly and take longer between molts than do those reared in a group. Although those groups can be too big “just as development is delayed in young cockroaches if they are isolated, over-crowding also extends the time between molts. So there is yet another kind of pheromone, called a “dispersal pheromone,” and it serves as the chemical signal that it is time to look for a new, slightly roomier harborage. This chemical is found in the insects’ saliva, and has just the opposite effect of the aggression attractant, in that it repulses cockroaches and causes them to look elsewhere for harborage.”

Radiation

In case you’re thinking we can just nuke the little critters you should know that cockroaches survived the atomic bombs test blast at Bikini. “There is such a thing as a lethal dose of radiation for a cockroach, but it is a lot higher than our own.”

Predators

“While few humans may eat them, the roach has both external and internal predators and parasites. There are centipedes that have a primary diet of cockroaches. Mantises, ants, and scorpions will eat them, as will a variety of larger animals including toads, frogs, possums, hedgehogs, armadillos, mongooses, monkeys, lizards, spiders, mice, cats, and birds”

Sleeping

Roaches are nocturnal and pass their days sleeping.

Male aggression

“Cockroaches, like so many other species including our own, have male aggression rituals. They have their own inventory of aggressive behaviors, a scale of conflict that begins with threatening postures. Beyond that they graduate to antenna lashing—a form of which is also present in male/female encounters to determine if a female is sexually receptive—and biting. Sex and territory seem to be the primary motivations for fighting between male cockroaches: These clashes never end in death, but always in the retreat of one fighter.”

Trapping a cockroach

“Stale white bread moistened with warm, slightly soured beer” is the most reliable and effective. “This is typically placed at the bottom of a small jar—a Gerber’s baby food jar, say—around the interior rim of which a petroleum jelly like Vaseline has been applied. The cockroach can climb in from the outside but can’t climb back out.”

What should you do if you get a cockroach stuck in your ear?

“It is, according to all accounts, painful and horrifying, although a little mineral oil or lidocaine sprayed into the ear is usually enough to dislodge the intruder.”

Exterminators

Exterminators primarily employ two methods to kill the cockroach: gas and gel. The gel is way more effective but many still rely on the spray. Why? “The major problem that exterminators have with the gel is that it has no immediate knockdown effect.”

John Wickham, an English pest control consultant defined knockdown as: “The inability of the insect to move in a sufficiently coordinated manner to right itself and progress normally.” When a roach eats gel bait—the safer of the two methods—it heads home before the active poison kills it.

“Customers who are paying \$75 an hour like to see these roaches struggling to get up, in agony and convulsions, and the sprays, with substantial knockdown effect, provide them that gratifying visual reassurance that the problem is being solved and that they are getting their money’s worth.

It’s unlikely this poison will have much long term impact. “Almost as soon as an effective poison goes into widespread use, cockroaches begin to develop Resistance. And,

typically, the most efficacious products developed, those that do the best job, turn out to be more detrimental to our own health than are the roaches.”

25. Too Many Decisions

The first thing you do in the morning is to make a decision. And those decisions pile up fast. Should I hit snooze? What clothes should I wear? What should I have for breakfast? What combination of choices from Starbucks will make my morning go smoother? You've already made more decisions than most of our ancestors would make in a day by the time you arrive at work. Unfortunately — at least as far as the quality of your decisions is concerned — your day is just getting started.

Decisions take a lot of mental effort. And that's a problem. Making choices reduces physical stamina, reduces persistence, reduces willpower, and even encourages procrastination.

John Tierney, adapted part of his upcoming book, *Willpower: Rediscovering the Greatest Human Strength*, for a New York Times Magazine article: Do You Suffer From Decision Fatigue?

Our brains are tired of making decisions. This has been coined as "Decision fatigue" and helps explain why, in the words of Tierney, "normally sensible people get angry at colleagues and families, splurge on clothes, buy junk food at the supermarket and can't resist the dealer's offer to rustproof their new car."

No matter how rational you are (or try to be), you can't make decision after decision without paying a mental price. "It's different", Tierney writes, "from ordinary physical fatigue — you're not consciously aware of being tired — but you're low on mental energy."

The more choices you make, the harder they become. To save energy your brain starts to look for shortcuts. One shortcut is to be reckless and act impulsively (rather than rationally). The other shortcut is to do nothing, which saves as much energy as possible (and often creates bigger problems in the long run).

It turns out that glucose is a vital part of willpower. Tierney writes, "Your brain does not stop working when glucose is low. It stops doing some things and starts doing others. It responds more strongly to immediate rewards and plays less attention to long-term prospects."

Glucose explains a lot. For instance, why people with phenomenally strong willpower in the rest of their lives struggle to lose weight. It also explains how someone can resist junk all day but gorge on a bag of chips right before bed. We start the day with a clean slate and the best intentions. It's fairly easy to resist fatty muffins at breakfast and skip the snickers bar fix after lunch. But each of these decisions—resistances—consumes glucose and lowers our willpower. Eventually, we need to replenish it. But that requires glucose, which creates a catch-22: We need willpower not to eat but in order to have willpower we need to eat.

Tierney continues, "when the brain's regulatory powers weaken, frustrations seem more irritating than usual. Impulses to eat, drink, spend and say stupid things feel more powerful (and alcohol causes self-control to decline further)...ego-depleted humans become more likely to get into needless fights over turf."

Although we have no way of knowing, it seems like a fairly safe bet that we make more decisions now than at any point in history. That is, we're under more decision making strain and we're starting to show cracks.

The internet and our ability to "multitask" isn't helping, argues Nicolas Carr, author of *The Shallows: What the Internet is Doing to Our Brain*: "A growing body of scientific evidence suggests that the Net, with its constant distractions and interruptions, is also turning us into scattered and superficial thinkers." Carr argues that our continuously connected, constantly distracted lives (read—constantly making decisions) rob us of the opportunity for deep thinking. The kind of thinking that we need to make a lot of decisions. By making thousands of trivial decisions every day, we rob ourselves of the ability to make more difficult contemplative decisions.

There are ways to improve our ability to make better decisions. Social psychologist Roy Baumeister has done research showing that people with the best self-control are the ones who structure their lives to conserve willpower. “They don’t,” Tierney suggests, “schedule endless back-to-back meetings. They avoid temptations like all-you-can-eat buffets, and they establish habits that eliminate the mental effort of making choices. Instead of deciding every morning whether or not to force themselves to exercise, they set up regular appointments to work out with a friend. Instead of counting on willpower to remain robust all day, they conserve it so that it’s available for emergencies and important decisions.” Wise advice we should all follow.

Organizations should start thinking carefully about how their employees actually end up spending their time and what they “waste” their precious mental energy on. If they’re filling out forms, trudging through a bureaucratic morass, or attending more than a few meetings a day, they’re likely using their mental energy on things that add little value to the organization.

26. Thomas Kuhn: The Structure of Scientific Revolutions

"The decision to reject one paradigm is always simultaneously the decision to accept another, and the judgment leading to that decision involves the comparison of both paradigms with nature and with each other."

The progress of science is commonly perceived of as a continuous, incremental advance, where new discoveries add to the existing body of scientific knowledge. This view of scientific progress, however, is challenged by the physicist and philosopher of science Thomas Kuhn, in his book The Structure of Scientific Revolutions. Kuhn argues that the history of science tells a different story, one where science proceeds with a series of revolutions interrupting normal incremental progress.

"A prevailing theory or paradigm is not overthrown by the accumulation of contrary evidence," Richard Zeckhauser wrote, "but rather by a new paradigm that, for whatever reasons, begins to be accepted by scientists."

Between scientific revolutions, old ideas and beliefs persist. These form the barriers of resistance to alternative explanations.

Zeckhauser continues "In this view, scientific scholars are subject to status quo persistence. Far from being objective decoders of the empirical evidence, scientists have decided preferences about the scientific beliefs they hold. From a psychological perspective, this preference for beliefs can be seen as a reaction to the tensions caused by cognitive dissonance. "

* * *

Gary Taubes posted an excellent blog post discussing how paradigm shifts come about in science. He wrote:

...as Kuhn explained in The Structure of Scientific Revolutions, his seminal thesis on paradigm shifts, the people who invariably do manage to shift scientific paradigms are "either very young or very new to the field whose paradigm they change... for obviously these are the men [or women, of course] who, being little committed by prior practice to the traditional rules of normal science, are particularly likely to see that those rules no longer define a playable game and to conceive another set that can replace them."

So when a shift does happen, it's almost invariably the case that an outsider or a newcomer, at least, is going to be the one who pulls it off. This is one thing that makes this endeavor of figuring out who's right or what's right such a tricky one. Insiders are highly unlikely to shift a paradigm and history tells us they won't do it. And if outsiders or newcomers take on the task, they not only suffer from the charge that they lack credentials and so credibility, but their work de facto implies that they know something that the insiders don't – hence, the idiocy implication.

...This leads to a second major problem with making these assessments – who's right or what's right. As Kuhn explained, shifting a paradigm includes not just providing a solution to the outstanding problems in the field, but a rethinking of the questions that are asked, the observations that are considered and how those observations are interpreted, and even the technologies that are used to answer the questions. In fact, often the problems that the new paradigm solves, the questions it answers, are not the problems and the questions that practitioners living in the old paradigm would have recognized as useful.

"Paradigms provide scientists not only with a map but also with some of the direction essential for map-making," wrote Kuhn. "In learning a paradigm the scientist acquires theory, methods, and standards together, usually in an inextricable mixture. Therefore, when paradigms change, there are usually significant shifts in the criteria determining the legitimacy both of problems and of proposed solutions."

As a result, Kuhn said, researchers on different sides of conflicting paradigms can barely discuss their differences in any meaningful way: "They will inevitably talk through each other when debating the relative merits of their respective paradigms. In the partially

circular arguments that regularly result, each paradigm will be shown to satisfy more or less the criteria that it dictates for itself and to fall short of a few of those dictated by its opponent."

But Taubes' explanation wasn't enough to satisfy my curiosity.

The Structure of Scientific Revolutions

To learn more on how paradigm shifts happen, I purchased Kuhn's book, The Structure of Scientific Revolutions, and started to investigate.

Kuhn writes:

"The decision to reject one paradigm is always simultaneously the decision to accept another, and the judgment leading to that decision involves the comparison of both paradigms with nature and with each other."

Anomalies are not all bad.

Yet any scientist who pauses to examine and refute every anomaly will seldom get any work done.

...during the sixty years after Newton's original computation, the predicted motion of the moon's perigee remained only half of that observed. As Europe's best mathematical physicists continued to wrestle unsuccessfully with the well-known discrepancy, there were occasional proposals for a modification of Newton's inverse square law. But no one took these proposals very seriously, and in practice this patience with a major anomaly proved justified. Clairaut in 1750 was able to show that only the mathematics of the application had been wrong and that Newtonian theory could stand as before. ... persistent and recognized anomaly does not always induce crisis. ... It follows that if an anomaly is to evoke crisis, it must usually be more than just an anomaly.

So what makes an anomaly worth the effort of investigation?

To that question Kuhn responds, "there is probably no fully general answer." Einstein knew how to sift the essential from the non-essential better than most.

When the anomaly comes to be recognized as more than another puzzle of science the transition, or revolution, has begun.

The anomaly itself now comes to be more generally recognized as such by the profession. More and more attention is devoted to it by more and more of the field's most eminent men. If it still continues to resist, as it usually does not, many of them may come to view its resolution as the subject matter of their discipline. ...

Early attacks on the anomaly will have followed the paradigm rules closely. As time passes and scrutiny increases, more of the attacks will start to diverge from the existing paradigm. It is "through this proliferation of divergent articulations," Kuhn argues, "the rules of normal science become increasingly blurred.

Though there still is a paradigm, few practitioners prove to be entirely agreed about what it is. Even formally standard solutions of solved problems are called into question."

Einstein explained this transition, which is the structure of scientific revolutions, best. He said: *"It was as if the ground had been pulled out from under one, with no firm foundation to be seen anywhere, upon which one could have built."*

All scientific crises begin with the blurring of a paradigm.

In this respect research during crisis very much resembles research during the pre-paradigm period, except that in the former the locus of difference is both smaller and more clearly defined. And all crises close in one of three ways. Sometimes normal science ultimately proves able to handle the crisis—provoking problem despite the despair of those who have seen it as the end of an existing paradigm. On other occasions the problem resists even apparently radical new approaches. Then scientists may conclude that no solution will be forthcoming in the present state of their field. The problem is labelled and set aside for a future generation with more developed tools. Or, finally, the case that will

most concern us here, a crisis may end up with the emergence of a new candidate for paradigm and with the ensuing battle over its acceptance.

But this isn't easy.

The transition from a paradigm in crisis to a new one from which a new tradition of normal science can emerge is far from a cumulative process, one achieved by an articulation or extension of the old paradigm. Rather it is a reconstruction of the field from new fundamentals, a reconstruction that changes some of the field's most elementary theoretical generalizations as well as many of its paradigm methods and applications.

Who solves these problems? Do the men and women who have invested a large portion of their lives in a field or theory suddenly confront evidence and change their mind? Sadly, no.

Almost always the men who achieve these fundamental inventions of a new paradigm have been either very young, or very new to the field whose paradigm they change. And perhaps that point need not have been made explicit, for obviously these are men who, being little committed by prior practice to the traditional rules of normal science, are particularly likely to see that those rules no longer define a playable game and to conceive another set that can replace them.

And

Therefore, when paradigms change, there are usually significant shifts in the criteria determining the legitimacy both of problems and of proposed solutions.

That observation returns us to the point from which this section began, for it provides our first explicit indication of why the choice between competing paradigms regularly raises questions that cannot be resolved by the criteria of normal science. To the extent, as significant as it is incomplete, that two scientific schools disagree about what is a problem and what is a solution, they will inevitably talk through each other when debating the relative merits of their respective paradigms. In the partially circular arguments that regularly result, each paradigm will be shown to satisfy more or less the criteria that it dictates for itself and to fall short of a few of those dictated by its opponent. There are other reasons, too, for the incompleteness of logical contact that consistently characterizes paradigm debates. For example, since no paradigm ever solves all the problems it defines and since no two paradigms leave all the same problems unsolved, paradigm debates always involve the question: Which problems is it more significant to have solved? Like the issue of competing standards, that questions of values can be answered only in terms of criteria that lie outside of normal science altogether.

Many years ago Max Planck offered this insight: "A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it."

27. The Decision-Making Flaw in Powerful People

The paper below finds a link between having a sense of power and ignoring the advice of others.

The authors argue that power increases confidence, which can lead to an excessive belief in one's own judgment.

In a sense, powerful people think they are right because of their place in the organization, not because of their knowledge.

This, of course, leads to flawed decisions.

From Strategy+Business:

Previous research has shown that the quality of decision making declines when people hew too much to their own beliefs and discount too readily the advice of others; outside information helps “average out” the distortions that can result when people give a great deal of weight to their own opinions and first impressions. This paper is among the first to examine whether power — defined as an individual’s “capacity to influence others, stemming in part from his or her control over resources, rewards, or punishments” — reduces or increases a person’s willingness to heed advice.

... In addition to confirming the previous experiments’ finding that more powerful people were less likely to take advice and were more likely to have high confidence in their answers, this final experiment showed that high-power participants were less accurate in their answers than low-power participants. By calculating the mean deviation between respondents’ initial estimates and the true answers, the researchers showed that low-power participants came significantly closer in their final estimates to the real tuition numbers because they “averaged” their initial guesses with the input from the advisors. The researchers propose that their findings have troubling implications for organizations — and that power could negatively affect not just advice taking, but also an individual’s approach to seeking help or accepting performance feedback. But because power and confidence are so interrelated, there are ways to mitigate the problem. By “directly addressing the inflated confidence levels of powerful individuals,” the researchers write, “organizations may be able to help people with power take (and/or seek) advice when it is valuable to do so.”

For one thing, organizations could formally include advice gathering at the earliest stages of the decision-making process, before powerful individuals have a chance to form their own opinions. Encouraging leaders to refrain from commenting on decisions publicly could also keep them from feeling wedded to a particular point of view.

Bottom Line:

Powerful people are less likely to take advice from others, in large part because they have high confidence in their own judgment and don’t feel the need to incorporate outside views. By not factoring in others’ advice, however, people in power risk making flawed decisions.

Abstract:

Incorporating input from others can enhance decision quality, yet often people do not effectively utilize advice. We propose that greater power increases the propensity to discount advice, and that a key mechanism explaining this effect is elevated confidence in one’s judgment. We investigate the relationships across four studies: a field survey where working professionals rated their own power and confidence and were rated by coworkers on their level of advice taking; an advice taking task where power and confidence were self-reported; and two advice taking experiments where power was manipulated. Results consistently showed a negative relationship between power and advice taking, and evidence of mediation through confidence. The fourth study also revealed that higher power participants were less accurate in their final judgments. Power can thus exacerbate

the tendency for people to overweight their own initial judgment, such that the most powerful decision makers can also be the least accurate.

28. Gary Klein: Streetlights and Shadows

Gary Klein's book Streetlights and Shadows looks at commonly held maxims for decision-making and overturns them, revealing cases where these practices break down. The book is an impressive look at why these problems occur and how we can become more resilient decision makers.

Here are ten beliefs that we hold about systems and decision making along with a proposed replacement.

1. *Teaching people procedures helps them perform tasks more skillfully.*

Replacement: In complex situations people will need judgment skills to follow procedures effectively and go beyond them when necessary.

2. *Decision biases distort our thinking.*

Replacement: Decision biases reflect our thinking. Rather than discouraging people from using heuristics, we should help them build expertise so they can use their heuristics more effectively.

2(a). *Successful decision makers rely on logic and statistics instead of intuition.*

Replacement: We need to blend systemic analysis and intuition.

3. *To make a decision, generate several options and compare them to pick the best one.*

Replacement: Good decision makers use their experience to recognize effective options and evaluate them through mental simulation.

4. *We can reduce uncertainty by gathering more information. Too much information can get in our way.*

Replacement: In complex environments, what we need isn't the right information but the right way to understand the information we have.

5. *It's bad to jump to conclusions – wait to see the evidence.*

Replacement: Speculate, but test your speculations instead of committing to them.

6. *To get people to learn, give them feedback on the consequences of their actions.*

Replacement: We can't just give feedback; we have to find ways to make it understandable.

7. *To make sense of a situation, we draw inferences from the data.*

Replacement: We make sense of data by fitting them into stories and other frames, but the reverse also happens: our frames determine what counts as data.

8. *The starting point for any project is a clear description of the goal.*

Replacement: When facing wicked problems, we should redefine goals as we try to reach them.

9. *Our plans will succeed more often if we identify the biggest risks and then find ways to eliminate them.*

B: We should cope with risk in complex situations by relying on resilience engineering rather than attempting to identify and prevent risks.

10. *Leaders can create common ground by assigning roles and setting ground rules in advance.*

Replacement: All team members are responsible for continually monitoring common ground for breakdowns and repairing the breakdown when necessary.

29. The Noise Bottleneck: When More Information is Harmful

When consuming information, we strive for more signal and less noise. The problem is a cognitive illusion: we feel like the more information we consume the more signal we receive.

While this is probably true on an absolute basis, Nassim Taleb argues in this excerpt from Antifragile, that it is not true on a relative basis. He calls it the noise bottleneck. Taleb argues that as you consume more data and the ratio of noise to signal increases, the less you know about what's going on and the more inadvertent trouble you are likely to cause.

The Institutionalization Of Neuroticism

Imagine someone of the type we call neurotic in common parlance. He is wiry, looks contorted, and speaks with an uneven voice. His necks moves around when he tries to express himself. When he has a small pimple his first reaction is to assume that it is cancerous, that the cancer is of the lethal type, and that it has already spread. His hypochondria is not just in the medical department: he incurs a small setback in business and reacts as if bankruptcy were both near and certain. In the office, he is tuned to every single possible detail, systematically transforming every molehill into a mountain. The last thing you want in life is to be in the same car with him when stuck in traffic on your way to an important appointment. The expression overreact was designed with him in mind: he does not have reactions, just overreactions.

Compare him to someone with the opposite temperament, imperturbable, with the calm under fire that is considered necessary to become a leader, military commander or a mafia godfather. Usually unruffled and immune to small information—they can impress you with their self-control in difficult circumstances. For a sample of a composed, call and pondered voice, listen to interview of “Sammy the Bull” Salvatore Gravano who was involved in the murder of nineteen people (all competing mobsters). He speaks with minimal effort. In the rare situations when he is angry, unlike with the neurotic fellow, everyone knows it and takes it seriously.

The supply of information to which we are exposed under modernity is transforming humans from the equable second fellow to the neurotic first. For the purpose of our discussion, the second fellow only reacts to real information, the first largely to noise. The difference between the two fellows will show us the difference between noise and signal. Noise is what you are supposed to ignore; signal what you need to heed.

Indeed, we have been loosely mentioning “noise” earlier in the book; time to be precise about it. In science, noise is a generalization beyond the actual sound to describe random information that is totally useless for any purpose, and that you need to clean up to make sense of what you are listening to. Consider, for examples, elements in an encrypted message that have absolutely no meaning, just randomized letters to confuse the spies, or the hiss you hear on a telephone line and that you try to ignore in order to just focus on the voice of your interlocutor.

Noise and Signal

If you want to accelerate someone's death, give him a personal doctor.

One can see from the tonsillectomy story that access to data increases intervention—as with neuroticism. Rory Sutherland signaled to me that those with a personal doctor on staff should be particularly vulnerable to naive interventionism, hence iatrogenics; doctors need to justify their salaries and prove to themselves that they have some work ethics, something “doing nothing” doesn't satisfy (Editor's note: the same forces apply to leaders, managers, etc.). Indeed at the time of writing the personal doctor or the late singer Michael Jackson is being sued for something that is equivalent to overintervention-to-stifle-antifragility (but it will take the law courts a while before they become familiar with the

concept). Conceivably, the same happened to Elvis Presley. So with overmedicated politicians and heads of state.

Likewise those in corporations or in policymaking (like *Fragilista Greenspan*) endowed with a sophisticated statistics department and therefore getting a lot of “timely” data are capable of overreacting and mistaking noise for information —Greenspan kept an eye on such fluctuations as the sales of vacuum cleaners in Cleveland “to get a precise idea about where the economy is going”, and, of course micromanaged us into chaos.

In business and economic decision-making, data causes severe side effects —data is now plentiful thanks to connectivity; and the share of spuriousness in the data increases as one gets more immersed into it. A not well discussed property of data: it is toxic in large quantities —even in moderate quantities.

The previous two chapters showed how you can use and take advantage of noise and randomness; but noise and randomness can also use and take advantage of you, particularly when totally unnatural —the data you get on the web or thanks to the media. The more frequently you look at data, the more noise you are disproportionately likely to get (rather than the valuable part called the signal); hence the higher the noise to signal ratio. And there is a confusion, that is not psychological at all, but inherent in the data itself. Say you look at information on a yearly basis, for stock prices or the fertilizer sales of your father-in-law’s factory, or inflation numbers in Vladivostok. Assume further that for what you are observing, at the yearly frequency the ratio of signal to noise is about one to one (say half noise, half signal) —it means that about half of changes are real improvements or degradations, the other half comes from randomness. This ratio is what you get from yearly observations. But if you look at the very same data on a daily basis, the composition would change to 95% noise, 5% signal. And if you observe data on an hourly basis, as people immersed in the news and markets price variations do, the split becomes 99.5% noise to .5% signal. That is two hundred times more noise than signal —which is why anyone who listens to news (except when very, very significant events take place) is one step below sucker.

There is a biological story with information. I have been repeating that in a natural environment, a stressor is information. So too much information would be too much stress, exceeding the threshold of antifragility. In medicine, we are discovering the healing powers of fasting, as the avoidance of too much hormonal rushes that come with the ingestion of food. Hormones convey information to the different parts of our system and too much of it confuses our biology. Here again, as with the story of the news received at too high a frequency, too much information becomes harmful. And in Chapter x (on ethics) I will show how too much data (particularly when sterile) causes statistics to be completely meaningless.

Now let’s add the psychological to this: we are not made to understand the point, so we overreact emotionally to noise. The best solution is to only look at very large changes in data or conditions, never small ones.

Just as we are not likely to mistake a bear for a stone (but likely to mistake a stone for a bear), it is almost impossible for someone rational with a clear, uninfected mind, one who is not drowning in data, to mistake a vital signal, one that matters for his survival, for noise. Significant signals have a way to reach you. In the tonsillectomies, the best filter would have been to only consider the children who are very ill, those with periodically recurring throat inflammation.

There was even more noise coming from the media and its glorification of the anecdote. Thanks to it, we are living more and more in virtual reality, separated from the real world, a little bit more every day, while realizing it less and less. Consider that every day, 6,200 persons die in the United States, many of preventable causes. But the media only reports the most anecdotal and sensational cases (hurricanes, freak incidents, small plane crashes) giving us a more and more distorted map of real risks. In an ancestral

environment, the anecdote, the “interesting” is information; no longer today. Likewise, by presenting us with explanations and theories the media induces an illusion of understanding the world.

*And the understanding of events (and risks) on the part of members of the press is so retrospective that they would put the security checks after the plane ride, or what the ancients call *post bellum auxilium*, send troops after the battle. Owing to domain dependence, we forget the need to check our map of the world against reality. So we are living in a more and more fragile world, while thinking it is more and more understandable. To conclude, the best way to mitigate interventionism is to ration the supply of information, as naturalistically as possible. This is hard to accept in the age of the internet. It has been very hard for me to explain that the more data you get, the less you know what’s going on, and the more iatrogenics you will cause.*

The noise bottleneck is really a paradox. We think the more information we consume the more signal we’ll consume. Only the mind doesn’t work like that. When the volume of information increases, our ability to comprehend the relevant from the irrelevant becomes compromised. We place too much emphasis on irrelevant data and lose sight of what’s really important.

30. An Algorithm for Solving Problems

“He (Richard Feynman) was always searching for patterns, for connections, for a new way of looking at something, but I suspect his motivation was not so much to understand the world as it was to find new ideas to explain. The act of discovery was not complete for him until he had taught it to someone else.”— Daniel Hillis

The Feynman Algorithm, which is a simplification of Richard Feynman’s technique to learn anything, is a good all purpose algorithm for solving problems. Cal Newport explains:

1. *Simplify the problem down to an “essential puzzle.” Here’s how Danny Hillis explained Feynman’s use of simplicity: “He always started by asking very basic questions like, ‘What is the simplest example?’ or ‘How can you tell if the answer is right?’ He asked questions until he reduced the problem to some essential puzzle that he thought he would be able to solve. Then he would set to work.”*
2. *Continually master new techniques and then apply them to your library of unsolved puzzles to see if they help. As mathematician Gian Carlo-Rota explained when describing Feynman’s use of this strategy: “Every once in a while there will be a hit, and people will say: ‘How did he do it? He must be a genius!’”*

31. Can Waiting Help You Make Better Decisions?

Great article in the financial times with the subtitle: Watching the world's best tennis players at Wimbledon over the next fortnight can help us make better decisions.

Here is what I learnt from interviewing more than 100 experts in different fields and working through several hundred recent studies and experiments: given the fast pace of modern life, most of us tend to react too quickly. We don't, or can't, take enough time to think about the increasingly complex timing challenges we face. Technology surrounds us, speeding us up. We overreact to its crush every day, both at work and at home.

And

*One of the most surprising aspects of Lehman's collapse was that the firm's leaders had tried so hard to understand the problems associated with their own decision-making. In autumn 2005, Lehman's senior managers hired a group of experts to teach four dozen top executives how to make better decisions. Max H Bazerman, a chaired professor at Harvard Business School, reviewed cutting-edge decision research. Mahzarin Banaji, a Harvard psychologist, administered custom-designed tests to help the executives understand their biases. Malcolm Gladwell, who had just published *Blink*, a bestseller about the "first two seconds" of our reactions, gave the capstone lecture.*

These managers sat for a cutting-edge course on the timing of decisions. Then, they rushed back to their offices and made some of the worst decisions in the history of financial markets. Three years later, their firm was gone.

If Lehman had lived until today, its decision-making course would look radically different.

The core message of recent research is the opposite of the one Lehman's executives learnt in 2005: the longer we can wait, the better. And once we have a sense of how long a decision should take, we generally should delay the moment of decision until the last possible instant. If we have an hour, we should wait 59 minutes before responding. If we have a year, we should wait 364 days. Even if we have just half a second, we should wait as long as we possibly can. As the matches at Wimbledon will illustrate, even milliseconds matter.

Thinking about the role of delay is a profound and fundamental part of being human.

Questions about delay are existential: the amount of time we take to reflect on decisions will define who we are. Is our mission simply to be another animal, responding to whatever stimulations we encounter? Or are we here for something more?

Life might be a race against time but it is enriched when we rise above our instincts and stop the clock to process and understand what we are doing and why. A wise decision requires reflection, and reflection requires a pause.

If we are limited to just one word of wisdom about decision-making for children born a hundred years from now, people who will have all our advantages and limitations as human beings but will need to navigate an unimaginably faster-paced world than the one we confront now, there is no doubt what that word should be.

Wait.

32. “When we encounter pain, we are at an important juncture in our decision-making process.”

It is a fundamental law of nature that to evolve one has to push one's limits, which is painful, in order to gain strength—whether it's in the form of lifting weights, facing problems head-on, or in any other way. Nature gave us pain as a messaging device to tell us that we are approaching, or that we have exceeded, our limits in some way. At the same time, nature made the process of getting stronger require us to push our limits. Gaining strength is the adaptation process of the body and the mind to encountering one's limits, which is painful. In other words, both pain and strength typically result from encountering one's barriers. When we encounter pain, we are at an important juncture in our decision-making process.

Most people react to pain badly. They have “fight or flight” reactions to it: they either strike out at whatever brought them the pain or they try to run away from it. As a result, they don't learn to find ways around their barriers, so they encounter them over and over again and make little or no progress toward what they want.

33. Benjamin Franklin's Rule for Making Decisions

When Charles Darwin set out to marry, he employed a technique pioneered half a century earlier by Ben Franklin. Despite his importance, the prolific Franklin often gave his practical wisdom to many of those who asked.

In the summer of 1772, Franklin received a letter from his friend, the English scientist, Joseph Priestley. Priestley was torn between relinquishing his position as the minister of the fame Unitarian church Mill Hill Chapel in Leeds and accepting a lucrative position as the general assistant to the Earl of Shelburne.

Like many of us faced with such a choice, Priestley was torn and turned to a friend for advice. Rather than simply offering advice on this particular choice, Franklin taught him something much more valuable: how to choose. By giving Priestley the simple mathematics of decision making, Franklin created what is now known as the pros and cons framework.

Franklin writes:

In the Affair of so much Importance to you, wherein you ask my Advice, I cannot for want of sufficient Premises, advise you what to determine, but if you please I will tell you how. When these difficult Cases occur, they are difficult chiefly because while we have them under Consideration all the Reasons pro and con are not present to the Mind at the same time; but sometimes one Set present themselves, and at other times another, the first being out of Sight. Hence the various Purposes or Inclinations that alternately prevail, and the Uncertainty that perplexes us.

To get over this, my Way is, to divide half a Sheet of Paper by a Line into two Columns, writing over the one Pro, and over the other Con. Then during three or four Days Consideration I put down under the different Heads short Hints of the different Motives that at different Times occur to me for or against the Measure. When I have thus got them all together in one View, I endeavour to estimate their respective Weights; and where I find two, one on each side, that seem equal, I strike them both out: If I find a Reason pro equal to some two Reasons con, I strike out the three. If I judge some two Reasons con equal to some three Reasons pro, I strike out the five; and thus proceeding I find at length where the Ballance lies; and if after a Day or two of farther Consideration nothing new that is of Importance occurs on either side, I come to a Determination accordingly.

And tho' the Weight of Reasons cannot be taken with the Precision of Algebraic Quantities, yet when each is thus considered separately and comparatively, and the whole lies before me, I think I can judge better, and am less likely to take a rash Step; and in fact I have found great Advantage from this kind of Equation, in what may be called Moral or Prudential Algebra.

Priestley accepted the position and science never looked back.

34. Michael Mauboussin: Two Tips to Improve The Quality of Your Decisions

Michael Mauboussin, chief investment strategist at Legg Mason and our [first interview on the podcast](#), offers two simple techniques to improve the quality of your decision making: a decision journal and a checklist.

1. Create a [decision journal](#) and starting using it.

Many years ago when I first met Danny Kahneman, and Kahneman is one of the preeminent psychologists in the world who won a Nobel Prize for economics in 2002, even though he's never taught an economics class.

When I pose him the question, what is a single thing an investor can do to improve his or her performance, he said almost without hesitation, go down to a local drugstore and buy a very cheap [notebook](#) and start keeping track of your decisions. And the specific idea is whenever you're making a consequential decision, something going in or out of the portfolio, just take a moment to think, write down what you expect to happen, why you expect it to happen and then actually, and this is optional, but probably a great idea, is write down how you feel about the situation, both physically and even emotionally. Just, how do you feel? I feel tired. I feel good, or this stock is really draining me. Whatever you think.

The key to doing this is that it prevents something called hindsight bias, which is no matter what happens in the world. We tend to look back on our decision-making process, and we tilt it in a way that looks more favorable to us, right? So we have a bias to explain what has happened.

When you've got a decision-making journal, it gives you accurate and honest feedback of what you were thinking at that time. And so there can be situations, by the way, you buy a stock and it goes up, but it goes up for reasons very different than what you thought was going to happen. And having that feedback in a way to almost check yourself periodically is extremely valuable. So that's, I think, a very inexpensive; it's actually not super time consuming, but a very, very valuable way of giving yourself essential feedback because our minds won't do it normally.

2. Use a checklist.

Mauboussin: So the [best work on this I've seen is by Atul Gawande](#), who is a surgeon in Boston who wrote a book a couple of years ago called [The Checklist Manifesto](#), and one of the points he makes in there is that when you go from field to field, wherever checklists have been used correctly and with fidelity, they've been extremely effective in proving outcomes. So we all know none of us would step on an airplane today without the pilot having gone through the checklist. It's been a big move into medicine, especially for example, in surgery where checklists have really made substantial inroads in reducing infections, for example, and hence mortality, and other areas like construction elsewhere. So the question is, how do you become more systematic in applying what you know? And I'll just mention one other thing on this. There are two; Gawande talks about two kinds of checklists. By the way, this branch is right out of aviation. One is called a do-confirm checklist, a do-confirm, and that just basically says, Hey, just do your normal analysis the way you've always done it and been trained to do that, but stop periodically just to confirm that you've covered all the bases. So as an analyst that might say, hey, I'm going to do a really thorough evaluation work. I might look very carefully at return on capital trends. I might study the competitive strategy position. You are just going to do all that stuff, but you're going to stop every now and then, just to check to make sure you've done everything.

The second one is called, the second kind of checklist, is called a read-do checklist. This is when you get into a difficult situation, for example you're a pilot and one of your engines goes out, the redo will guide how you should approach that problem. So you don't have to

think about it so much, you just sort of go through it systematically. And so for an investor that might be hey, what happens when a company misses a quarter? What happens when they have a negative announcement or an executive departure? Sometimes that means sell the stock. Sometimes that means buy more. Sometimes it means do nothing, and a read-do checklist can help guide some of that thinking as well. So it's really a way to be structured and consistent in your analysis.

35. The Checklist Manifesto: How to Get Things Right

It's no secret that I'm a huge fan of Atul Gawande. A reader recently pointed out that I hadn't covered his most recent book, *The Checklist Manifesto: How to Get Things Right*. I had only covered an interesting subset of the book—why we fail.

The Checklist Manifesto

To put us in the proper context, we're smart. Not scary smart but smart enough. We have skills, and we generally put them in the most highly trained and hardworking people we can find. We have the most educated society in history. And we've accomplished a lot. Nevertheless, sometimes, success escapes us for avoidable reasons. Not only are these failures common—across everything from medicine to finance—but they are also frustrating. We should know better, but we don't. The reason we don't learn, Gawande argues, is evident:

the volume and complexity of what we know has exceeded our individual ability to deliver its benefits correctly, safely, or reliably. Knowledge has both saved us and burdened us.

To overcome this, we need a strategy. Something that “builds on experience and takes advantage of the knowledge people have but somehow also makes up for our inevitable human inadequacies.” We need a checklist.

In response to increasing complexity, we've become more specialized. We divide the problem up. It's not just the growing breadth and quantity of knowledge that makes things more complicated, although they certainly are significant contributors. It is also execution. In every field from medicine to construction, there are a slew of practical procedures, policies, and best practices. Gawande breaks this down for the modern medical case:

[Y]ou have a desperately sick patient and in order to have a chance of saving him you have to get the knowledge right and then you have to make sure that the 178 daily tasks that follow are done correctly—despite some monitor's alarm going off for God knows what reason, despite the patient in the next bed crashing, despite a nurse poking his head around the curtain to ask whether someone could help “get this lady's chest open.” There is complexity upon complexity. And even specialization has begun to seem inadequate. So what do you do?

The response of the medical profession, like most others, is to move from specialization to super-specialization. Gawande argues that these super-specialists have two advantages over ordinary specialists: greater knowledge of the things that matter and “a learned ability to handle the complexities of that particular job.” But even for these super specialists, avoiding mistakes is proving impossible.

Modern professions, like medicine, with their dazzling successes and spectacular failures, pose a significant challenge: “What do you do when expertise is not enough? What do you do when even the super-specialists fail?”

The origins of the checklist.

On October 30, 1935, at Wright Air Field in Dayton, Ohio, the U.S. Army Air Corps held a competition for airplane manufacturers vying to build the next-generation of the long-range bomber. Only it wasn't supposed to be much of a competition at all. The Boeing Corporation's gleaming aluminum-alloy Model 299 was expected to steal the show, its design far superior to those of the competition. In other words, it was just a formality. As the Model 299 test plane taxied onto the runway, a small group of army brass and manufacturing executives watched. The plane took off without a hitch. Then suddenly, at about 300 feet, it stalled, turned on one wing, and crashed killing two of the five crew members, including the pilot Major Hill.

Of course, everyone wanted to know what had happened. An investigation revealed that there was nothing to indicate any problems mechanically with the plane. It was a “pilot error.” The problem with the new plane, if there was one, was that it was substantially more complex than the previous aircraft. Among other things, there were 4 engines, each

with its own fuel-mix, wing flaps, trim that needed constant adjustment, and propellers requiring pitch adjustment. While trying to keep up with the increased complexity, Hill had forgotten to release a new locking mechanism on the rudder controls. The new plane was too much for anyone to fly. The unexpected winner was the smaller designed Douglas. Here is where it really gets interesting. The army, convinced of the technical superiority of the plane, ordered a few anyway. If you're thinking they'd just put the pilots through more training to fly the plane, you'd be wrong. Major Hill, the chief of flight testing, was an experienced pilot, so longer training was unlikely to result in improvement. Instead, they created a pilot's checklist.

The pilots made the list simple and short. It fit on an index card with step-by-step instructions for takeoff, flying, landing, and taxiing. It was as if someone all of a sudden gave an experienced automobile driver a checklist of things that would be obvious to them. There was nothing on the checklist they didn't know. Stuff like, check that the instruments are set, the door closed. Basics. That checklist changed the course of history and quite possibly the war. The pilots went on to fly the Model 299 a "total of 1.8 million miles" without a single accident and as a result the army ordered over 13,000 of them.

In *The Checklist Manifesto*, Gawande argues that most of today's work has entered a checklist phase.

Substantial parts of what software designers, financial managers, firefighters, police officers, lawyers, and most certainly clinicians do are now too complex for them to carry out reliably from memory alone.

Yet, no one wants to use a checklist. We believe "our jobs are too complicated to reduce to a checklist." After all, we don't work at McDonald's, right?

In a complex environment, experts are up against two main difficulties. The first is the fallibility of human memory and attention, especially when it comes to mundane, routine matters that are easily overlooked under the strain of more pressing events. (When you've got a patient throwing up and an upset family member asking you what's going on, it can be easy to forget that you have not checked her pulse.) Faulty memory and distraction are a particular danger in what engineers call all-or-none processes: whether running to the store to buy ingredients for a cake, preparing an airplane for takeoff, or evaluating a sick person in the hospital, if you miss just one key thing, you might as well not have made the effort at all.

A further difficulty, just as insidious, is that people can lull themselves into skipping steps even when they remember them. In complex processes, after all, certain steps don't always matter. ... "This has never been a problem before," people say. Until one day it is. Checklists seem to provide protection against such failures. They remind us of the minimum necessary steps and make them explicit. They not only offer the possibility of verification but also instill a kind of discipline of higher performance.

In news that would shock bureaucracies and governments alike, the strategy a lot of industries use to get things right in complex environments is to give employees power. Most authorities, in response to risk, tend to centralize power and decision making. Sometimes that's even the point of a checklist—to make sure the people below you are doing things in the manner in which you want. These checklists, the McDonald's type checklists, spell out the tiniest detail of every critical step. These serve their purpose, but they also create a group of employees no longer able to adapt. When things change, as they always do, you're now faced with a non-routine problem. "The philosophy," writes Gawande, "is that you push the power of decision making out to the periphery and away from the center. You give people the room to adapt, based on their experience and expertise. All you ask is that they talk to one another and take responsibility. That is what works."

...the real lesson is that under conditions of true complexity—where the knowledge required exceeds that of any individual and unpredictability reigns—efforts to dictate every

step from the center will fail. People need room to act and adapt. Yet they cannot succeed as isolated individuals, either—that is anarchy. Instead, they require a seemingly contradictory mix of freedom and expectation—expectation to coordinate, for example, and also to measure progress toward common goals.

This was the understanding people in the skyscraper-building industry had grasped. More remarkably, they had learned to codify that understanding into simple checklists. They had made the reliable management of complexity a routine.

That routine requires balancing a number of virtues: freedom and discipline, craft and protocol, specialized ability and group collaboration. And for checklists to help achieve that balance, they have to take two almost opposing forms. They supply a set of checks to ensure the stupid but critical stuff is not overlooked, and they supply another set of checks to ensure people talk and coordinate and accept responsibility while nonetheless being left the power to manage the nuances and unpredictabilities the best they know how.

I came away from Katrina and the builders with a kind of theory: under conditions of complexity, not only are checklists a help, they are required for success. There must always be room for judgment, but judgment aided—and even enhanced—by procedure.

36. The Two Types of Knowledge: The Max Planck/Chauffeur Test

Charlie Munger, the billionaire business partner of Warren Buffett, frequently tells the story below to illustrate how to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

At the 2007 Commencement to the USC Law School, Munger explained it this way:

I frequently tell the apocryphal story about how Max Planck, after he won the Nobel Prize, went around Germany giving the same standard lecture on the new quantum mechanics. Over time, his chauffeur memorized the lecture and said, "Would you mind, Professor Planck, because it's so boring to stay in our routine. [What if] I gave the lecture in Munich and you just sat in front wearing my chauffeur's hat?" Planck said, "Why not?" And the chauffeur got up and gave this long lecture on quantum mechanics. After which a physics professor stood up and asked a perfectly ghastly question. The speaker said, "Well I'm surprised that in an advanced city like Munich I get such an elementary question. I'm going to ask my chauffeur to reply."

The point of the story is not the quick-wittedness of the protagonist, but rather — to echo Richard Feynman — it's about making a distinction between knowing the name of something and knowing something.

Two Types of Knowledge

The first type of knowledge is real. It can't be bought. It can't be copied. If you want real knowledge you need to earn it. The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work.

Munger continues:

In this world we have two kinds of knowledge. One is Planck knowledge, the people who really know. They've paid the dues, they have the aptitude. And then we've got chauffeur knowledge. They've learned the talk. They may have a big head of hair, they may have fine temper in the voice, they'll make a hell of an impression.

But in the end, all they have is chauffeur knowledge. I think I've just described practically every politician in the United States.

And you are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge.

And there are huge forces working against you. My generation has failed you a bit... but you wouldn't like it to be too easy now would you?

Real knowledge comes when people do the work. On the other hand, we have the people who don't do the work — they pretend. While they've learned to put on a good show, they lack understanding. They can't answer questions that don't rely on memorization. They can't explain things without using jargon or vague terms. They have no idea how things interact. They can't predict the consequences.

"Any fool can know. The point is to understand."

— Albert Einstein

The problem is that it's difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.

In The Art of Thinking Clearly, Rolf Dobelli offers some commentary on distinguishing fake from real knowledge:

With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the

tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and — often as compensation for their patchy knowledge— snarky and self-satisfied in tone. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case.

One way to guard against this is to understand your circle of competence.

Dobelli concludes with some advice worth taking to heart.

Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

Sorting through the people with real knowledge from those that do not is so important that Elon Musk tries to tease it out in interviews.

37. Why Bad Things Happen to Good Decisions

Good decisions don't always have a good outcome, just as bad decisions don't always have bad outcomes. Sometimes bad outcomes happen to good decisions. And sometimes good things happen to bad decisions. Learning to distinguish between when you're brilliant and lucky is the key to rapid improvement.

When other people make decisions with bad outcomes, we tend to focus on the people behind the decision. We can't seem to shake the belief that good people make good decisions and bad people make bad decisions. It's easy to think that we would have made a better decision.

When our decisions have bad outcomes, we know the outcomes is not all there is to see. Our thoughts and intentions come into play. We can't see the thoughts and intentions of others—we only see their actions through a biased lens. We can, however, see our thoughts and intentions. Our bad outcomes happen because we were unlucky.

The Decision Outcome Matrix

Consider this simple two-by-two decision outcome matrix.

	Good Outcome	Bad Outcome
Good Process	What we are aiming for.	We are not omniscient. We need courage to weather this. Your system will not work every time, and it is easy to abandon the system the first time it fails.
Bad Process	Gambling and winning. Feeds the halo effect.	Gambling and losing. My bad luck, your poor skill.

We want to deserve success. Everyone wants to be in the upper left box — a good process that results in a good outcome. The problem is the world doesn't always comply with our wishes. Following a good process can lead to a bad outcome because of uncertainty.

A good process with a bad outcome requires that we remember nothing is for sure. Bad outcomes from a bad process require a choice. If we are delusional and let our ego dominate, we mistakenly see this as bad luck. While we are aware that we had a negative outcome, we are unaware that it resulted from a bad process. In this case, we learn nothing. We are doomed to repeat our mistakes. More self-reflective people see bad

outcomes resulting from bad process as an opportunity to learn as much as we can to avoid repeat failures.

Perhaps the worst quadrant to be in is the lower left — a bad process leads to a good outcome. Ignoring the fact that this isn't repeatable, we convince ourselves that we deserved success.

If you can't recognize when you've had 'dumb luck,' you'll never be in a position to correct the way you're making decisions. Eventually, your luck runs out.

Of course, it's easier to place others into the matrix than ourselves. When it comes to others, we see more of reality because we're a disconnected observer. When it comes to ourselves, however, we default to ego protection.

One of the ways to calibrate your decisions is to use a decision journal. A good decision is known *before* the outcome. It involves a mental representation of the facts known at the time as well as applied judgment. Good decisions are valuable, but they are more valuable if they are part of a good decision process because a good process allows for feedback about where you can improve. This feedback, in turn, allows you to constantly get better at making decisions.

Article Summary:

- Good decisions don't always have a good outcome. Bad decisions don't always have bad outcomes.
- Bad outcomes can happen to good decisions.
- When other people have a bad outcome, we tend to think they made a bad decision. When we have a bad outcome, we tend to focus on intentions.
- There is a simple 2*2 matrix to help you see what happened. On one axis is Good/Bad Process, on the other is good/bad outcome.
- A bad process with a good outcome is gambling and winning. This is the most dangerous quadrant.
- A bad process with a bad outcome is gambling and losing.
- A good process with a bad outcome needs to be put into perspective.
- You can calibrate your decisions using a decision journal.

38. Mental Model: Game Theory

From Game Theory, by Morton Davis:

The theory of games is a theory of decision making. It considers how one should make decisions and to a lesser extent, how one does make them. You make a number of decisions every day. Some involve deep thought, while others are almost automatic. Your decisions are linked to your goals—if you know the consequences of each of your options, the solution is easy. Decide where you want to be and choose the path that takes you there. When you enter an elevator with a particular floor in mind (your goal), you push the button (one of your choices) that corresponds to your floor. Building a bridge involves more complex decisions but, to a competent engineer, is no different in principle. The engineer calculates the greatest load the bridge is expected to bear and designs a bridge to withstand it. When chance plays a role, however, decisions are harder to make. ... Game theory was designed as a decision-making tool to be used in more complex situations, situations in which chance and your choice are not the only factors operating. ... (Game theory problems) differ from the problems described earlier—building a bridge and installing telephones—in one essential respect: While decision makers are trying to manipulate their environment, their environment is trying to manipulate them. A store owner who lowers her price to gain a larger share of the market must know that her competitors will react in kind. ... Because everyone's strategy affects the outcome, a player must worry about what everyone else does and knows that everyone else is worrying about him or her.

What is a game? From Game Theory and Strategy:

Game theory is the logical analysis of situations of conflict and cooperation. More specifically, a game is defined to be any situation in which:

- 1. There are at least two players. A player may be an individual, but it may also be a more general entity like a company, a nation, or even a biological species.*
- 2. Each player has a number of possible strategies, courses of action which he or she may choose to follow.*
- 3. The strategies chosen by each player determine the outcome of the game.*
- 4. Associated to each possible outcome of the game is a collection of numerical payoffs, one to each player. These payoffs represent the value of the outcome to the different players.*

...Game theory is the study of how players should rationally play games. Each player would like the game to end in an outcome which gives him as large a payoff as possible.

From Greg Mankiw's Economics textbook:

Game theory is the study of how people behave in strategic situations. By 'strategic' we mean a situation in which each person, when deciding what actions to take, must consider how others might respond to that action. Because the number of firms in an oligopolistic market is small, each firm must act strategically. Each firm knows that its profit depends not only on how much it produces but also on how much the other firms produce. In making its production decision, each firm in an oligopoly should consider how its decision might affect the production decisions of all other firms.

Game theory is not necessary for understanding competitive or monopoly markets. In a competitive market, each firm is so small compared to the market that strategic interactions with other firms are not important. In a monopolized market, strategic interactions are absent because the market has only one firm. But, as we will see, game theory is quite useful for understanding the behavior of oligopolies.

A particularly important 'game' is called the prisoners' dilemma.

Markets with only a few sellers

Because an oligopolistic market has only a small group of sellers, a key feature of oligopoly is the tension between cooperation and self-interest. The oligopolists are best off when they cooperate and act like a monopolist – producing a small quantity of output and charging a price above marginal cost. Yet because each oligopolist cares only about its own profit, there are powerful incentives at work that hinder a group of firms from maintaining the cooperative outcome.

Avinash Dixit and Barry Nalebuff, in their book “Thinking Strategically” offer:

Everyone’s best choice depends on what others are going to do, whether it’s going to war or maneuvering in a traffic jam.

These situations, in which people’s choices depend on the behavior or the choices of other people, are the ones that usually don’t permit any simple summation. Rather we have to look at the system of interaction.

Michael J. Mauboussin relates game theory to firm interaction

How a firm interacts with other firms plays an important role in shaping sustainable value creation. Here we not only consider how many companies interact with their competitors, but how companies can co-evolve.

Game Theory is one of the best tools to understand interaction. Game Theory forces managers to put themselves in the shoes of other players rather than viewing games solely from their own perspective.

The classic two-player example of game theory is the prisoners’ dilemma.

38. Blindness to the Benefits of Ambiguity

“Decision makers,” write Stefan Trautmann and Richard Zeckhauser in their paper Blindness to the Benefits of Ambiguity, “often prove to be blind to the learning opportunities offered by ambiguous probabilities. Such decision makers violate rational decision making and forgo significant expected payoffs.”

Trautmann and Zeckhauser argue that we often don’t recognize the benefits in commonly occurring ambiguous situations. In part this is because we often treated repeated decisions involving ambiguity as one-shot decisions. In doing so, we ignore the opportunity for learning when we encounter ambiguity in decisions that offer repeat choices.

To put this in context, the authors offer the following example:

A patient is prescribed a drug for high cholesterol. It is successful, lowering her total cholesterol from 230 to 190, and her only side effect is a mild case of sweaty palms. The physician is likely to keep the patient on this drug as long as her cholesterol stays low. Yet, there are many medications for treating cholesterol. Another might lower her cholesterol even more effectively or impose no side effects. Trying an alternative would seem to make sense, since the patient is likely to be on a cholesterol medication for the rest of her life.

In situations of ambiguity with repeated choices we often gravitate towards the first decision that offers a positive payoff. Once we’ve found a positive payoff we’re likely to stick with that decision when given the opportunity to make the same choice again rather than experiment in an attempt to optimize payoffs. We ignore the opportunity for learning and favor the status quo. Another way to think of this is uncertainty avoidance (or ambiguity aversion).

Few individuals recognize that ambiguity offers the opportunity for learning. If a choice situation is to be repeated, ambiguity brings benefits, since one can change one’s choice if one learns the ambiguous choice is superior.

“We observe,” they offer, “that people’s lack of a clear understanding of learning under ambiguity leads them to adopt non-Bayesian rules.”

Another example of how this manifests itself in the real world:

In the summer of 2010, the consensus estimate is that there are five applicants for every job opening, yet major employers who expect to hire significant numbers of workers once the economy turns up are sitting by the sidelines and having current workers do overtime. The favorability of the hiring situation is unprecedented in recent years. Thus, it would seem to make sense to hire a few workers, see how they perform relative to the norm. If the finding is much better, suggesting that the ability to select in a very tough labor market and among five applicants is a big advantage, then hire many more. This situation, where the payoff to the first-round decision is highly ambiguous, but perhaps well worthwhile once learning is taken into account, is a real world exemplar of the laboratory situations investigated in this paper.

...

According to Tolstoi, happy families are all alike, while every unhappy family is unhappy in its own way. A similar observation seems to hold true for situations involving ambiguity: There is only one way to capitalize correctly on learning opportunities under ambiguity, but there are many ways to violate reasonable learning strategies.

From an evolutionary perspective, why would learning avoidance persist if the benefits from learning are large?

Psychological findings suggest that negative experiences are crucial to learning, while good experiences have virtually no pedagogic power. In the current setting, ambiguous options would need to be sampled repeatedly in order to obtain sufficient information on whether to switch from the status quo. Both bad and good outcomes would be experienced along the way, but only good ones could trigger switching. Bad outcomes would also weigh much more heavily, leading people to require too much positive evidence

before shifting to ambiguous options. In individual decision situations, losses often weigh 2 to 3 times as much as gains.

In addition, if one does not know what returns would have come from an ambiguous alternative, one cannot feel remorse from not having chosen it. Blame from others also plays an important role. In principal-agent relationships, bad outcomes often lead to criticism, and possibly legal consequences because of responsibility and accountability. Therefore, agents, such as financial advisors or medical practitioners may experience an even higher asymmetry from bad and good payoffs. Most people, for that reason, have had many fewer positive learning experiences with ambiguity than rational sampling would provide.

It might be a good idea to try a new brand the next time you're at the store rather than just making the same choice over and over. Who knows, you might discover you like it better.

39. Insensitivity To Base Rates: An Introduction

In statistics, a base rate refers to the percentage of a population (e.g. grasshoppers, people who live in New York, newborn babies) which have a characteristic. Given a random individual and no additional information, the base rate tells us the likelihood of them exhibiting that characteristic. For instance, around 10% of people are left-handed. If you selected a random person and had no information related to their handedness, you could safely guess there to be a 1 in 10 chance of them being left-handed.

When we make estimations, we often fail to consider the influence of base rates. This is a common psychological bias and is related to the representativeness heuristic.

From Smart Choices: A Practical Guide to Making Better Decisions:

Donald Jones is either a librarian or a salesman. His personality can best be described as retiring. What are the odds that he is a librarian?

When we use this little problem in seminars, the typical response goes something like this: "Oh, it's pretty clear that he's a librarian. It's much more likely that a librarian will be retiring; salesmen usually have outgoing personalities. The odds that he's a librarian must be at least 90 percent." Sounds good, but it's totally wrong.

The trouble with this logic is that it neglects to consider that there are far more salesmen than male librarians. In fact, in the United States, salesmen outnumber male librarians 100 to 1. Before you even considered the fact that Donald Jones is "retiring," therefore, you should have assigned only a 1 percent chance that Jones is a librarian. That is the base rate.

Now, consider the characteristic "retiring." Suppose half of all male librarians are retiring, whereas only 5 percent of salesmen are. That works out to 10 retiring salesmen for every retiring librarian — making the odds that Jones is a librarian closer to 10 percent than to 90 percent. Ignoring the base rate can lead you wildly astray.

* * *

Charlie Munger, instructs us how to think about base rates with an example of an employee who got caught for stealing, claiming she's never done it before and will never do it again:

You find an isolated example of a little old lady in the See's Candy Company, one of our subsidiaries, getting into the till. And what does she say? "I never did it before, I'll never do it again. This is going to ruin my life. Please help me." And you know her children and her friends, and she'd been around 30 years and standing behind the candy counter with swollen ankles. When you're an old lady it isn't that glorious a life. And you're rich and powerful and there she is: "I never did it before, I'll never do it again." Well how likely is it that she never did it before? If you're going to catch 10 embezzlements a year, what are the chances that any one of them — applying what Tversky and Kahneman called base rate information — will be somebody who only did it this once? And the people who have done it before and are going to do it again, what are they all going to say? Well in the history of the See's Candy Company they always say, "I never did it before, and I'm never going to do it again." And we cashier them. It would be evil not to, because terrible behavior spreads (Greshams law).

* * *

Max Bazerman, in Judgment in Managerial Decision Making, writes:

(Our tendency to ignore base rates) is even stronger when the specific information is vivid and compelling, as Kahneman and Tversky illustrated in one study from 1972. Participants were given a brief description of a person who enjoyed puzzles and was both mathematically inclined and introverted. Some participants were told that this description was selected from a set of seventy engineers and thirty lawyers. Others were told that the description came from a list of thirty engineers and seventy lawyers. Next, participants were asked to estimate the probability that the person described was an engineer. Even

though people admitted that the brief description did not offer a foolproof means of distinguishing lawyers from engineers, most tended to believe the description was of an engineer. Their assessments were relatively impervious to differences in base rates of engineers (70 percent versus 30 percent of the sample group.)

Participants do use base-rate data correctly when no other information is provided. In the absence of a personal description, people use the base rates sensibly and believe that a person picked at random from a group made up mostly of lawyers is most likely to be a lawyer. Thus, people understand the relevance of base-rate information, but tend to disregard such data when individuating data are also available.

Ignoring base rates has many unfortunate implications. ... Similarly, unnecessary emotional distress is caused in the divorce process because of the failure of couples to create prenuptial agreements that facilitate the peaceful resolution of a marriage. The suggestion of a prenuptial agreement is often viewed as a sign of bad faith. However, in far too many cases, the failure to create prenuptial agreements occurs when individuals approach marriage with the false belief that the high base rate for divorce does not apply to them.

** * **

Of course, this applies to investing as well. This conversation with Sanjay Bakshi speaks to this:

One of the great lessons from studying history is to do with “base rates”. “Base rate” is a technical term of describing odds in terms of prior probabilities. The base rate of having a drunken-driving accident is higher than those of having accidents in a sober state.

So, what’s the base rate of investing in IPOs? When you buy a stock in an IPO, and if you flip it, you make money if it’s a hot IPO. If it’s not a hot IPO, you lose money. But what’s the base rate – the averaged out experience – the prior probability of the activity of subscribing for IPOs – in the long run?

If you do that calculation, you’ll find that the base rate of IPO investing (in fact, it’s not even investing ... it’s speculating) sucks! [T]hat’s the case, not just in India, but in every market, in different time periods.

[...]

When you evaluate whether smoking is good for you or not, if you look at the average experience of 1,000 smokers and compare them with a 1,000 non-smokers, you’ll see what happens.

People don’t do that. They get influenced by individual stories like a smoker who lived till he was 95. Such a smoker will force many people to ignore base rates, and to focus on his story, to fool themselves into believing that smoking can’t be all that bad for them.

What is the base rate of investing in leveraged companies in bull markets?

[...]

This is what you learn by studying history. You know that the base rate of investing in an airline business sucks. There’s this famous joke about how to become a millionaire. You start with a billion, and then you buy an airline. That applies very well in this business. It applies in so many other businesses.

Take the paper industry as an example. Averaged out returns on capital for paper industry are bad for pretty good reasons. You are selling a commodity. It’s an extremely capital intensive business. There’s a lot of over-capacity. And if you understand microeconomics, you really are a price taker. There’s no pricing power for you. Extreme competition in such an environment is going to cause your returns on capital to be below what you would want to have.

It’s not hard to figure this out (although I took a while to figure it out myself). Look at the track record of paper companies around the world, and the airline companies around the world, or the IPOs around the world, or the textile companies around the world. Sure, there’ll be exceptions. But we need to focus on the average experience and not the

exceptional ones. The metaphor I like to use here is that of a pond. You are the fisherman. If you want to catch a lot of fish, then you must go to a pond where there's a lot of fish. You don't want to go to fish in a pond where there's very little fish. You may be a great fisherman, but unless you go to a pond where there's a lot of fish, you are not going to find a lot of fish.

[...]

So one of the great lessons from studying history is to see what has really worked well and what has turned out to be a disaster – and to learn from both.

40. An Ancient Lesson on Taking Responsibility For Decisions

"A decision is responsible," wrote Charles Frankel, "when the man or group that makes it has to answer for it to those who are directly or indirectly affected by it."

Think about that for a second.

How often does that happen today? Not very often.

In most organizations people don't make decisions — committees do. Responsibility is diffused to a group, not the individual. Everyone is insulated from their mistakes. Everyone takes credit for success.

The ancients had a way around this. Consider Hammurabi's Code:

If a builder builds a house for a man and does not make its construction firm, and the house which he has built collapses and causes the death of the owner of the house, that builder shall be put to death.

While extreme, that is the best risk-management rule ever. If you have the upside, you have to keep the downside.

The Roman System

The Romans had a similar system.

The guy who created the arch stood under it as the scaffolding was removed. And to some extent, we do the same thing today. No one packs your parachute for you.

Charlie Munger, the partner of Warren Buffett at Berkshire Hathaway, puts it another way:

Another thing that is never discussed any more is my idea of one of the great philosophers of America who was Charlie Frankel. He was mugged to death in due course because, after all, he lived in Manhattan in a different time. Before he was mugged to death, he created this philosophy of responsibility. He said the system is responsible in proportion to the degree that the people who make the decisions bear the consequences.

So to Charlie Frankel, you don't create a loan system where all the people who make the loans promptly dump them on somebody else through lies and twaddle, and they don't bear the responsibility when the loans are good or bad. To Frankel, that is amoral, that is an irresponsible system. That is like selling an automobile with bad brakes and you know the brakes are bad. You shouldn't do it.

We've gotten away from responsibility for our decisions, which allows people to get all the upside and none of the downside. Is it any wonder why things go wrong?

How can we implement better decisions in organizations? Make people stand under their own arches. One effective way to implement this is to make the person responsible for a decision sign their name to the decision. Simple and effective but not easy to implement.

41. Making Smart Choices: 8 Keys to Making Effective Decisions

Making decisions is a fundamental life skill. Expecting to make perfect decisions all of the time is unreasonable. When even an ounce of luck is involved, good decisions can have bad outcomes. So our goal should be to raise the odds of making a good decision. The best way to do that is to use a good decision-making process.

Smart Choices: A Practical Guide to Making Better Decisions contains an interesting decision-making framework: PrOACT.

We have found that even the most complex decision can be analysed and resolved by considering a set of eight elements. The first five—

Problem, Objectives, Alternatives, Consequences, and Tradeoffs—constitute the core of our approach and are applicable to virtually any decision. The acronym for these—PrOACT—serves as a reminder that the best approach to decision situations is a proactive one. ... The three remaining elements—uncertainty, risk tolerance, and linked decisions—help clarify decisions in volatile or evolving environments.

This framework can help you make better decisions. Of course, sometimes good decisions go wrong. A good decision, however, increases the odds of success.

There are eight keys to effective decision making.

Work on the right decision problem. ... The way you frame your decision at the outset can make all the difference. To choose well, you need to state your decision problems carefully, acknowledging their complexity and avoiding unwarranted assumptions and option-limiting prejudices. ...

Specify your objectives. ... A decision is a means to an end. Ask yourself what you most want to accomplish and which of your interests, values, concerns, fears, and aspirations are most relevant to achieving your goal. ... Decisions with multiple objectives cannot be resolved by focusing on any one objective.

Create imaginative alternatives. ... Remember: your decision can be no better than your best alternative. ...

Understand the consequences. ... Assessing frankly the consequences of each alternative will help you to identify those that best meet your objectives—all your objectives. ...

Grapple with your tradeoffs. Because objectives frequently conflict with one another, you'll need to strike a balance. Some of this must sometimes be sacrifices in favor of some of that. ...

Clarify your uncertainties. What could happen in the future and how likely is it that it will? ...

Think hard about your risk tolerance. When decisions involve uncertainties, the desired consequence may not be the one that actually results. A much-deliberated bone marrow transplant may or may not halt cancer. ...

Consider linked decisions. What you decide today could influence your choices tomorrow, and your goals for tomorrow should influence your choices today. Thus many important decisions are linked over time. ...

Harvard Professor Max Bazerman, who has written extensively human misjudgment, suggests something very similar to this approach in his book Judgment in Management Decision Making when he explains the anatomy of decisions. Before we can fully understand judgment, we have to identify the components of the decision-making process that require it. Here are the six steps that Bazerman argues you should take, either implicitly or explicitly, when applying a rational decision-making process.

42. Cognitive Dissonance and Change Blindness

“Their judgment was based more on wishful thinking than on a sound calculation of probabilities; for the usual thing among men is that when they want something they will, without any reflection, leave that to hope, while they will employ the full force of reason in rejecting what they find unpalatable.”

— Thucydides, in History of the Peloponnesian War

From Stalking the Black Swan: Research and Decision Making in a World of Extreme Volatility

When new information conflicts with our preexisting hypotheses, we have a problem that needs to be resolved. Cognitive dissonance refers to the state of tension that occurs when a person holds two ideas, beliefs, attitudes, or opinions that are psychologically inconsistent. This conflict manifests itself as a state of mental tension or dissonance, the intensity of which is visible in magnetic resonance imaging studies of the brain. The theory was developed in 1957 by Leon Festinger, who observed in a series of experiments that people would change their attitudes to make them more consistent with actions they had just taken. In popular usage, cognitive dissonance refers to the tendency to ignore information that conflicts with preexisting views, to rationalize certain behaviors to make them seem more consistent with self-image, or to change attitudes to make them consistent with actions already taken. In some cases, it is the equivalent of telling ourselves “little white lies,” but in other cases it no doubt contributes to logical errors like the “confirmation trap,” where people deliberately search for data to confirm existing views rather than challenge them.

Two major sources of cognitive dissonance are self-image (when the image we hold of ourselves is threatened) and commitment (when we’ve said something, we don’t want to be criticized for changing our minds).

“Cognitive dissonance,” writes Ken Posner, “may manifest itself in a phenomenon known as change blindness. According to behavioral researches”:

change blindness is a situation where people fail to notice change because it takes place slowly and incrementally. It is also called the “boiling frog syndrome,” referring to the folk wisdom that if you throw a frog in boiling water it will jump out, but if you put it into cold water that is gradually heated, the frog will never notice the change. Most of the studies in this area focus on difficulties in perceiving change visually, but researchers think there is a parallel to decision making.

“Change blindness,” Posner continues, “happens when we filter out the implications of new information rather than assigning them even partial weight in our thinking.”

43. Michael Mauboussin: Untangling Skill and Luck in Business, Sports, and Investing

In *The Success Equation: Untangling Skill and Luck in Business, Sports, and Investing*, Michael Mauboussin goes beyond the general idea that luck is important to outcomes. He explains the type of interactions where luck is important and dives into why we have a difficult time comprehending the role of luck.

“The basic challenge,” he writes, “is that we love stories (narrative fallacy) and have a yearning to understand the relationship between cause and effect. As a result, statistical reasoning is hard, and we start to view the past as something that was inevitable.”

Mauboussin goes on to explain how we should untangle skill and luck so we can get a feel for where they fall on the luck-skill continuum. “Where an activity falls on that continuum,” he writes “provides a great deal of insight into how to deal with it.” Skill tends to follow an arc – improving, stagnating, and then ultimately going lower.

In activities where the results are independent of one another, simple models effectively explain what we see. But when a past result affects a future result, predicting winners becomes very difficult. The most skillful don't always win.

TABLE 4-1

The contribution of luck in some professional sports leagues

League	Contribution of luck	Five seasons ended
National Basketball Association	12%	2011
Premier League	31%	2011
Major League Baseball	34%	2011
National Football League	38%	2011
National Hockey League	53%	2012

Source: Analysis by author.

Source: The Success Equation

As a sports fan, I enjoyed the breakdown of the contribution of luck in some professional sports leagues:

And something to keep in mind, “the contribution of luck has been rising steadily over time in most sports, which means that the players are all converging on an equal level of skill.” Although, this doesn't apply to basketball.

On automatic decision making, Mauboussin writes:

The problem with this sort of automatic decision-making apparatus is that it only works under very specific circumstances. Intuition works when the environment is stable and an individual has the opportunity to spend a great deal of time learning about it. . . . Trouble arises when individuals rely too heavily on their experience in making automatic decisions. When we age, we tend to avoid exerting too much cognitive effort and deliberating

extensively over a decision that needs to be made. We gradually come to rely more on rule of thumb. This means that we make poorer choices in environments that are complex and unstable.

Organizations also lose skill with age.

Probably the best explanation for why companies decline is that they fall prey to organizational rigidities. Companies must balance exploiting profitable markets with exploring new markets. Exploiting known markets requires optimizing processes and executing effectively, and leads to reliable, near-term successes. Exploring unknown markets requires search and experimentation and offers none of the immediate benefits of exploitation.

Finding the best balance between exploration and exploitation depends on the rate of change in the environment. When change comes slowly, the balance can tilt toward exploitation. When it comes quickly, an organization must dedicate more resources to exploration, since profits are quickly exhausted. In general, companies tend to lean more on exploitation, which increases efficiency and profits in the short run but makes the company rigid, a state of affairs that only grows worse with age. Similar to aging individuals, companies rely on methods and rules of thumb that worked well in the past rather than embrace novelty. Companies, too, follow an arc of skill.

The book is full of tips. Deliberate practice helps develop differentiating skill when only a little luck is involved in the outcome. That is, the larger the impact of skill on the outcome, the more effective deliberate practice becomes. On the other hand, “where luck is rampant,” he writes, “we must think of skill in terms of a process because the results don’t provide clear feedback.”

Checklists, are also important because they guide behavior.

Sometimes, of course, you want to defend against luck. If you’re a heavy favorite, you want to neutralize the other teams luck, so your aim should be to simplify the game. When you’re the underdog you want to make the game as complex as possible. Effort and strategy can compensate for skill.

44. Richard Zeckhauser on Making Better Decisions

Richard Zeckhauser, aka Mr. Probability, is a champion Bridge player and the Frank Ramsey professor of political economy at Harvard University.

Speaking about Zeckhauser, Charlie Munger, the brilliant business partner of Warren Buffett, said, “The right way to think is the way Zeckhauser plays bridge. It’s just that simple.”

In an interview, Zeckhauser offers some insights on the craft of decision making about where to place your priorities and how to distinguish between various priorities.

When asked how companies can prevent overpaying for acquisition, Zeckhauser responded:

There is this tremendous optimism bias built into acquisitions. Synergies in my experience are frequently overstated. If I were looking at a large merger, I would hire a team in my corporation to present arguments to the board as to why we should not do it. The idea is to have a countervailing team to poke holes in the logic. Organizations have this tremendous tendency to get behind the boss and do what he thinks should be done, but you have to get away from that and motivate people to bring to the table something contrary to what is being said.

That bit of wisdom applies to more than just corporate acquisitions. The problem is that people often blindly follow the boss and what s/he thinks should be done. The Hippo Problem. — The Highest Paid Person’s Opinion carries the day even if they are wrong. They are, after all, the authority figure.

Stanley Milgram demonstrated our obedience to authority through a series of experiments. Milgram summarized his most famous experiment in a 1974 article, The Perils of Obedience, writing:

I set up a simple experiment at Yale University to test how much pain an ordinary citizen would inflict on another person simply because he was ordered to by an experimental scientist. Stark authority was pitted against the subjects’ [participants’] strongest moral imperatives against hurting others, and, with the subjects’ [participants’] ears ringing with the screams of the victims, authority won more often than not. The extreme willingness of adults to go to almost any lengths on the command of an authority constitutes the chief finding of the study and the fact most urgently demanding explanation.

Ordinary people, simply doing their jobs, and without any particular hostility on their part, can become agents in a terrible destructive process. Moreover, even when the destructive effects of their work become patently clear, and they are asked to carry out actions incompatible with fundamental standards of morality, relatively few people have the resources needed to resist authority

Zeckhauser also commented on how we can make better decisions?

One part of decision-making is about how to place your priorities. Let me tell you what I said to a group of investment professionals recently. They were making investments and were being introduced to five fund managers. I said, “You have \$50 million to invest and you have five potential managers; that does not mean you have to give \$10 million to each of these managers. If you really think that manager A is much better, you should probably give him \$25m and the others much smaller amounts.” Then, you improve your odds.

Here’s another example out of what I see in everyday life. You get 50 e-mails during the day and you answer 30 of them. On the one that you answer the most, you take 3 minutes. In all the others, you take 45 seconds. You should take 25 minutes to answer the one that is important, but you don’t. Once that is pointed out to you, you will say that is really obvious. In other words, you should decide what is really important and make your choices accordingly.

The other thing is about distinguishing between various probabilities. I think of making decisions the way I play tennis. I have taken many tennis lessons and my trainer always

tells me the same three or four things. Keep your eye on the ball, get into position, swing your racquet back and swing the ball. I pay him \$75 to tell me “keep your eye on the ball” and he tells me the same thing over and over again because the natural tendency when you are playing tennis is to take your eye off the ball. The natural tendency when you are thinking about probabilistic situations is to marginalise probabilities — treat 1%, 5%, 10% and 15% probabilities all as low probabilities. I think it is worth your while before you take a decision to figure out whether it is going to be 1%, 5%, 10% or 20%. And when it is worthwhile and when it is not. But most people don't bother to do that.

I am writing a paper today where we start off talking about President Obama's assessment of the likelihood that Osama bin Laden was in the hideout where we found him to be. He had a variety of assessments and he eventually concluded well it was 50% likely that we were going to go get him. Now, there is nothing magical about 50%. It might be that it is perfectly worthwhile to go and raid that compound if the probability is only 30%. And maybe it is not worthwhile even if it is 70%. Think about that. But people feel that 50% is magical and they don't like to do things where they don't have 50% odds. I know that is not a good idea, so I am willing to make some bets where you say it is 20% likely to work but you get a big pay-off if it works, and only has a small cost if it does not. I will take that gamble. Most successful investments in new companies are where the odds are against you but, if you succeed, you will succeed in a big way.

45. What Matters More in Decisions: Analysis or Process?

We all make decisions. Some of them are large and many of them are small. Few of us understand that the process we use to make those decisions is more important than the analysis we put into the decision.

Think of the last major decision you made.

Maybe it was an acquisition, a large purchase, or perhaps it was whether to launch a new product.

Odds are three things went into that decision: (1) It probably relied on the insights of a few key executives; (2) it involved some sort of fact gathering and analysis; and (3) it was likely enveloped in some sort of decision process—whether formal or informal—that translated the analysis into a decision.

Now how would you rate the *quality* of your organization's strategic decisions?

If you're like most executives, the answer wouldn't be positive:

In a recent McKinsey Quarterly survey of 2,207 executives, only 28 percent said that the quality of strategic decisions in their companies was generally good, 60 percent thought that bad decisions were about as frequent as good ones, and the remaining 12 percent thought good decisions were altogether infrequent.

How could it be otherwise? Product launches are frequently behind schedule and over budget. Strategic plans often ignore even the anticipated response of competitors.

Mergers routinely fail to live up to the promises made in press releases.

The persistence of problems across time and organizations, both large and small, indicates that we can make better decisions.

"I have no use whatsoever for projections or forecasts. They create an illusion of apparent precision. The more meticulous they are, the more concerned you should be. We never look at projections."

— Warren Buffett

The best place to start if we're trying to improve the quality of our decisions is to look at how organizations make decisions. One interesting thing about bureaucracies is that they develop processes to limit the damage the worst people can do at every level. That is they come up with mechanisms to reduce the impact the worst people can have. Yes, this also limits the positive impact that people can have as well. When it comes to decisions, organizations default to gathering data and analyzing decisions.

The widespread belief is that analysis reduces biases. But does it?

Is putting your faith in analysis any better than using your gut? What does the evidence say? Is there a better way?

Dan Lovallo and Olivier Sibony set to find out.

Lovallo is a professor at the University of Sydney and Olivier is a director at McKinsey & Company. Together they studied 1,048 "major" business decisions over five years. The results are surprising.

Most business decisions were not made on "gut calls" but rather rigorous analysis. And yet they were poor decisions. In short, most people did the all the legwork we think we're supposed to do: they delivered large quantities of detailed analysis.

Yet this wasn't enough. "Our research indicates that, contrary to what one might assume, good analysis in the hands of managers who have good judgment won't naturally yield good decisions."

[Projections] are put together by people who have an interest in a particular outcome, have a subconscious bias, and its apparent precision makes it fallacious. They remind me of Mark Twain's saying, 'A mine is a hole in the ground owned by a liar.' Projections in America are often a lie, although not an intentional one, but the worst kind because the forecaster often believes them himself."

Lovallo and Sibony didn't only look at the analysis, they also asked executives about the process used to make decisions.

Did they, for example, "explicitly explore and discuss major uncertainties or discuss viewpoints that contradicted the senior leader's?"

So what matters more, process or analysis? After comparing the results they determined that "process mattered more than analysis—by a factor of six."

This finding does not mean that analysis is unimportant, as a closer look at the data reveals: almost no decisions in our sample made through a very strong process were backed by very poor analysis. Why? Because one of the things an unbiased decision-making process will do is ferret out poor analysis. The reverse is not true; superb analysis is useless unless the decision process gives it a fair hearing.

To illustrate the weakness of how most organizations make decisions, Sibony used an interesting analogy: the legal system.

Imagine walking into a courtroom where the trial consists of a prosecutor presenting PowerPoint slides. In 20 pretty compelling charts, he demonstrates why the defendant is guilty. The judge then challenges some of the facts of the presentation, but the prosecutor has a good answer to every objection. So the judge decides, and the accused man is sentenced.

That wouldn't be due process, right? So if you would find this process shocking in a courtroom, why is it acceptable when you make an investment decision? Now of course, this is an oversimplification, but this process is essentially the one most companies follow to make a decision. They have a team arguing only one side of the case. The team has a choice of what points it wants to make and what way it wants to make them. And it falls to the final decision maker to be both the challenger and the ultimate judge. Building a good decision-making process is largely ensuring that these flaws don't happen.

Simply understanding our cognitive biases doesn't make you immune to them. It's not enough. A disciplined decision process is the best place to improve the quality of decisions and guard against common decision-making biases.

46. The Four Villains of Decision Making

You're probably not as effective at making decisions as you could be.

This article explores Chip and Dan Heath's new book, Decisive. It's going to help us make better decisions both as individuals and in groups.

But before we get to that, you should think about a tough decision you're grappling with right now. Having a decision working in your mind as you're reading this post will help make the advice in here tangible.

Ok, let's dig in.

"A remarkable aspect of your mental life is that you are rarely stumped ... The normal state of your mind is that you have intuitive feelings and opinions about almost everything that comes your way. You like or dislike people long before you know much about them; you trust or distrust strangers without knowing why; you feel that an enterprise is bound to succeed without analyzing it."

— Daniel Kahneman

We're quick to jump to conclusions because we give too much weight to the information in front of us and we fail to search for new information, which might disprove our thoughts.

Nobel Prize winning Psychologist Daniel Kahneman called this tendency "what you see is all there is." But that's not the only reason we don't make good decisions — there are many others.

We're overconfident. We look for information that fits our thoughts and ignore information that doesn't. We are overly influenced by authority. We choose the short-term over the long-term. Once we've made a decision we find it hard to change our mind. In short, our brains are flawed. I could go on.

Knowing about these and other biases isn't enough; it doesn't help us fix the problem. We need a framework for making decisions.

In Decisive, the Heaths introduce a four-step process designed to counteract many biases. In keeping with Kahneman's visual metaphor, the Heaths refer to the tendency to see only what's in front of us as a "spotlight" effect.

And that, in essence, is the core difficulty of decision making.

What's in the spotlight will rarely be everything we need to make good decisions, but we won't always remember to shift the light.

Most of us rarely use a process for thinking about things. If we do use one it's likely to be the pros-and-cons list. While better than nothing, this approach is still deeply flawed because it doesn't really account for biases.

The Four Villains of Decision Making

1. **Narrow Framing:** "... the tendency to define our choices too narrowly, to see them in binary terms. We ask, "Should I break up with my partner or not?" instead of "What are the ways I could make this relationship better?"
2. **Confirmation Bias:** "When people have the opportunity to collect information from the world, they are more likely to select information that supports their preexisting attitudes, beliefs, and actions." We pretend we want the truth, yet all we really want is reassurance.
3. **Short-term Emotion:** "When we've got a difficult decision to make, our feelings churn. We replay the same arguments in our head. We agonize about our circumstances. We change our minds from day to day. If our decision was represented on a spreadsheet, none of the numbers would be changing—there's no new information being added—but it doesn't feel that way in our heads."
4. **Overconfidence:** "People think they know more than they do about how the future will unfold."

The Heaths came up with a process to help us overcome these villains and make better choices. “We can’t deactivate our biases, but ... we can counteract them with the right discipline.” The nature of each of the four decision-making villains suggests a strategy for how to defeat it.

1. *You encounter a choice. But narrow framing makes you miss options. So ... Widen Your Options. How can you expand your set of choices? ...*

2. *You analyze your options. But the confirmation bias leads you to gather self-serving information. So ... Reality-Test Your Assumptions. How can you get outside your head and collect information you can trust? ...*

3. *You make a choice. But short-term emotion will often tempt you to make the wrong one. So ... Attain Distance Before Deciding. How can you overcome short-term emotion and conflicted feelings to make better choices? ...*

4. *Then you live with it. But you’ll often be overconfident about how the future will unfold. So ... Prepare to Be Wrong. How can we plan for an uncertain future so that we give our decisions the best chance to succeed? ...*

They call this WRAP. “At its core, the WRAP model urges you to switch from “auto spotlight” to manual spotlight.

Source: Decisive

All in all this was a great book. We focus our efforts on analysis. If a decision is wrong the analysis must have been the problem. Not only does this ignore the fact that you can have ‘bad outcomes’ with good decisions but it also places your spotlight on the analysis at the cost of the process by which the decision was made.

47. Decision Making Psychology with Rory Sutherland

Below are three excerpts from a great interview with Rory Sutherland on decision making psychology.

Understanding Human Behavior

That attempt to model economic behaviour as though it were Newtonian physics was responsible for many past mistakes. This is closer to weather forecasting than to conventional physics as a science. But it is still a science and can still make progress like a science. And the great news is that we are starting from such a low base. If our ability to understand and predict human behaviour only improves by a few percent a decade, the benefits will be immense. And even a tiny reduction in misdirected effort (by abandoning daft, ineffectual sunk-cost-plagued endeavours such as the war on drugs or, at a more modest level, badly conceived choice-architectures in a new range of cars) all can be economically transformative.

The Physical Fallacy

The problem we all face is “The physical fallacy”. All of us, even those the social sciences, have an innate bias where we are happier fixing problems with stuff, rather than with psychological solutions – building faster trains rather than putting wifi on existing trains, to use my oft cited example. But as Benjamin Franklin (no mean decision scientist himself) remarked “There are two ways of being happy: We must either diminish our wants or augment our means – either may do. The result is the same and it is for each man to decide for himself and to do that which happens to be easier.”

There is no reason to prefer one solution over another simply because it involves solid matter rather than grey matter. This is an interesting area where the advertising industry and the environmental movement (rarely seen as natural bedfellows) sometimes find common ground. Intangible value is the best kind of value – since the materials needed to create it are not in short supply.

Marketing and Advertising

If you need to understand why marketing and advertising (and reputation and brands) are important to the functioning of markets, Akerlof’s paper “The Market for Lemons” is essential reading. So too is his excellent and underread book “Identity Economics” written with Rachel Kranton. The problem is not with economics as practiced by great economists – it is the unquestioning adherence to the dumber assumptions of Basic Economics 101 as unthinkingly absorbed by the product of a thousand business schools.

You are particularly made aware of the pernicious influence of bad economics if you work in advertising. Even when advertising demonstrably works and is highly cost effective, people in finance and in the boards of companies don’t seem to like it very much. Since they have a mental model of the world in which everyone has perfect information, they have of course constructed in their heads a vision of the world in which marketing shouldn’t exist.

48. The Munger Two Step

A simple and easy approach to decision making that prevents us from being manipulated.

1. Understand the forces at play.
2. Understand how your subconscious might be leading you astray.

While most of us make decisions daily, few of us have a useful framework for thinking that protects us when making decisions.

We're going to explore Munger's two-step process for making effective decisions and reducing human misjudgment.

In A Lesson on Elementary Worldly Wisdom, Charlie Munger offers a simple two-step filter for making effective decisions:

Personally, I've gotten so that I now use a kind of two-track analysis. First, what are the factors that really govern the interests involved, rationally considered? And second, what are the subconscious influences where the brain at a subconscious level is automatically doing these things-which by and large are useful, but which often malfunction.

One approach is rationality-the way you'd work out a bridge problem: by evaluating the real interests, the real probabilities and so forth. And the other is to evaluate the psychological factors that cause subconscious conclusions-many of which are wrong.

Let's take a closer look.

1. The Forces at Play

The key to the first step is knowing what you know and what you don't know. You need to understand your circle of competence. It's just as important to know what you don't know as it is to know what you know.

If you know what you don't know, you might still have to make a decision, but your approaches for making that decision will change. For example, if you're forced to make a decision in an area that you know is well outside your circle of competence, one tool you can use is inversion.

While there are millions of factors that go into decisions, there will always be a few variables and factors that will carry the bulk of the weight. If you're operating within your circle of competence, it should be relatively easy to figure out the relevant variables and forces at play.

I can't tell you the relevant variables. There is no magic formula. To make consistently good decisions, you need to develop a deep fluency in the area in which you are making decisions, and you need to pull in the big ideas from multiple disciplines to make sure you're exercising good judgment.

2. The Psychological Factors

There are many causes of human misjudgment, including over-confidence. These are the subtle ways that your mind might be leading you astray at a subconscious level. Your subconscious mind is larger than your conscious mind, and yet we rarely pay attention to how we might be tricking ourselves. One way to mislead yourself, for instance, is to make decisions based on a small sample size and extrapolate the results to a larger population. Another way we fool ourselves is to remain committed to something we've said in the past. We might rely on an authority figure or default to what everyone else is doing. You get the idea.

Usually, when we have extreme success or failure, there are four or five factors working in the same direction. The same goes for psychology. The more human misjudgment factors there are working against us, the more likely we are to make an ill-informed decision.

49. Understanding and Diagnosing Problems

We all know one, the Monday morning quarterback.

They walk into the meeting room primed and ready for action. Ready that is, to apply the knowledge they know now to decisions of the past. And too often we're defenseless.

The outcome by now is likely apparent to everyone.

"When a decision goes awry," writes Albert Bernstein in his book Dinosaur Brains, "we tend to focus on the people who made it, rather than on the decision itself. Our assumption, which is really unwarranted, is that good people make good decisions, and vice versa."

The point is to focus on what was known at the time. And consider, in light of that, was it a reasonable decision?

Good decisions don't always have a good outcome, just as bad decisions don't always have bad outcomes. It's scary but a lot of otherwise smart people are unable to distinguish the difference.

This image from our rethink conference on decision making helps us understand what's going on.

	Good Outcome	Bad Outcome
<i>Good Process</i>	What we are aiming for.	We are not omniscient. We need courage to weather this. Your system will not work every time, and it is easy to abandon the system the first time it fails.
<i>Bad Process</i>	Gambling and winning. Feeds the halo effect.	Gambling and losing. My bad luck, your poor skill.

RE:THINKING DECISIONS

fs

It's easy to shine the spotlight on the outcome. It doesn't involve a lot of thinking either and it certainly isn't going to help you understand or diagnose problems.

It's harder, yet profitable, to think back and evaluate the merits of a particular decision based on what was known at the time. Was it a good decision with a bad outcome?

But usually, the only information we have about how and why decisions were made is the self-serving memories of the people in the room. "We have very little vocabulary for talking about internal thought processes," writes James March, "Decisions feel as if they jump fully grown from one's head."

This is where having a good decisionprocess comes in. Keeping a decision journals is also helpful.

Maybe executives in responsible positions should be required to keep logs, as sea captains do. After each decision, a manager would list his or her reasons for having made it and record how it turned out.

If you have a journal, you can pull it out and see, in light of the facts and assumptions at the time, whether the best decision possible was made and if there was, in fact, a mistake. If there really was a mistake, you can look at your decision process and determine what went wrong and how to avoid it in the future. Don't hide mistakes behind vagueness but, equally important, stay away from the blame/credit mentality because it undermines understanding. And understanding is the key to getting better.

One way to reinforce good decisions is to document the assumptions at the time the decision is made in a decision journal.

50. How to Make Smart Decisions Without Getting Lucky

Few things will change your trajectory in life or business as much as learning to make effective decisions. Yet no one really teaches us what it means to make consistently high-quality decisions.

The decision-making principles in this article are both practical and time-tested. They work in the real world.

In this guide, we'll cover:

- [No One Taught you How to Decide](#)
- [Your Mind is a Pattern Matching Machine](#)
- [Decision Making](#)
- [Smart People Make Terrible Decisions](#)
- [Sources of Stupidity](#)
- [Intelligent Preparation: The World Is Multidisciplinary](#)
- [How We Make Decisions](#)
- [General Thinking Concepts](#)
- [Add To Your Decision-Making Skills](#)
- [Books to Improve Decisions](#)

Ready? Ok, Let's dig in.

No one Taught you How to Decide

I started working at an intelligence agency on August 28, 2001. Two weeks later, the world would never be the same.

My computer science degree lost its value after a few promotions. I came from a world of 1s and 0s, not people, families, and interpersonal dynamics.

Just out of school, I found that my decisions affected not only my employees but their families. Not only my country but other countries. However, there was one small problem. I had no idea how to make smart decisions. I had no idea how to reduce errors. I only knew I had an obligation to make the best decisions I could. But where do you start?

There is no class called "decision making." Making better decisions isn't one skill but rather a series of tools and frameworks. What distinguishes consistently good decision-makers from poor ones is a series of diverse mental frameworks and tools (as well as relevant specific information).

Most of us operate like a carpenter with only a hammer. To a man with a hammer, every problem looks like a nail. No matter the job, we pull out our hammer and attempt to make it work. While a hammer can often get the job done eventually, it comes with a cost. In my world, a poor decision could cost lives, impact my country, or even start a war. A hammer wasn't enough, I wanted more tools.

"The older I get the more I realize how many kinds of smart there are. There are a lot of kinds of smart. There are a lot of kinds of stupid, too."

— JeFF Bezos

To fill my mental toolbox, I looked around my organization and found some mentors. I watched them, asked them annoying questions, and tried to learn as much as I could from them. I went back to school to get an MBA. I read everything I could about making decisions and the tools I needed to develop.

Thanks to the internet, I was no longer limited to the best teachers in my organization or university. The entire world was available. I could find the best teachers in the world, learn their tools and frameworks, and add them to my mental toolbox.

Pattern Matching

You probably don't know it but you already think in mental models. Mental models are mental chunks of knowledge that represent a concept. Gravity is a model. So are probabilistic thinking, inversion, and entropy.

Mental models shape how you think, how you approach problems, and how you identify the information that matters and ignore what doesn't. The mental models in your head are your cognitive skillset.

Decision Making

Think about the state of your life, your career, your business, your major relationships — anything consequential to you.

How many important decisions have you already had to make? With the benefit of hindsight, how well did you make them?

How many decisions did you make today? How did you make these decisions? Is there a better way?

Not all decisions matter. Most decisions, like where to grab a sandwich, are unimportant. The consequences of these decisions don't matter.

Yet some decisions are critical — they change our lives. Whether its who to trust, where to live, or whom to marry, these decisions reverberate for years.

Yet most of us don't have the right skills to think through these problems. As a result, we often fall back to the pro-con list, where you list all the positive things that happen on one side and the negative things on the other trading them off.

While useful when deciding what to have for lunch, the pro-con list comes with a lot of blind spots.

"I regard it as a criminal waste of time to go through the slow and painful ordeal of ascertaining things for one's self if these same things have already been ascertained and made available by others."

— Thomas Edison

SMART People Make Terrible Decisions

Otherwise smart people can make terrible decisions. Think about decisions like these:

- Napoleon decided to invade Russia (and Hitler did it again 130 years later)
- An editor deciding to publish O.J Simpson's *If I Did It*

- Chris Webber choosing the timeout he didn't have in the 1993 Final Four
- NASA's decision to ignore the O-ring issues on the Challenger
- President Kennedy's famous blunder to continue the Bay of Pigs operation inherited from the previous administration (a mistake he quickly learned from)
- Margaret Thatcher deciding to get behind a "poll tax" that led to her ouster by her own party
- Juergen Schrempp, the CEO of Daimler-Benz, deciding to merge with Chrysler despite massive internal opposition and general history of big M&A deals working very poorly
- Jim Cramer looking at Bear Stearns in 2007 and calling it a "BUY"
- ...and a hundred thousand more...

These were catastrophic decisions made by people who were, in some sense, professional decision-makers. They had impeccable credentials and judgment, and yet they made poor decisions due to poor judgment, a too-limited mental representations of the world, or just plain stupidity.

Sources of Stupidity

There are a lot of reasons we fail to make effective decisions.

Let's take a look at five of the biggest ones:

1. We're unintentionally stupid. I like to think that I'm rational and capable of interpreting all information in a non-biased way but that's a dream. Cognitive biases are great at explaining how our evolutionary programming leads us astray. Knowledge of these biases in advance rarely helps us make better decisions. There are, however, many easily recognizable situations that increase the odds we're about to do something stupid. Whether we're tired, overly focused on a goal, rushing, distracted, operating in a group, or under the influence of a group, we're more prone to stupidity.²
2. We have the wrong information. Making decisions with the wrong assumptions or facts is likely to lead to disaster.
3. We use the wrong model. We use mental models to make decisions. The quality of those models determines the quality of our thinking. There are a variety of reasons that we use false, incomplete, or incorrect models. Novices are prone to using models that the expert knows are incomplete or irrelevant. The odds of employing the wrong models increase as the pace of environmental change increases.
4. We fail to learn. We all know the person that has 20 years of experience but it's really the same year over and over. Well, that person is sometimes us. If we don't understand how we learn, we're likely to make the same mistakes over and over.
5. Looking over doing good. Our evolutionary programming conditions us to do what's easy over what's right. After all it's often easier to signal being virtuous than actually being virtuous. We unconsciously make choices based on optics, politics, and defendability. We hate criticism and seek the validation of our peers and superiors. We often want to feel good about ourselves first and have the outcome we desire second.

Luckily, we can take steps to reduce the odds of stupidity and increase the odds of good decisions in each of these categories.

"The frog in the well knows nothing of the mighty ocean."

— Japanese Proverb

Intelligent Preparation: The World Is Multidisciplinary

We live in a society that demands specialization. Being the best means being an expert in something. Letters after your name and decades in the trenches of experience are required before you can claim to know anything. In one sense there is nothing wrong with this — specialized knowledge is required to solve problems and advance our global

potential. But a byproduct of this niche focus is that it narrows the ways we think we can apply our knowledge without being called a fraud.

So we think physicists can't teach us about love; mathematicians can't instruct us on how to run a business; poets don't know squat about "my life." And bloggers can't contribute to philosophy.

I don't believe this is true.

Knowledge is hard to come by.

It takes work and commitment, and I think we owe it to ourselves to take it out of the box it comes in and experiment with it. We should blow past conformity and apply all the knowledge at our disposal to the problems and challenges we face every day.

Think about it. Over time you've picked up a lot of fundamentals about how the world works. You may have read a book about the Manhattan Project and the building of the nuclear bomb that was launched at Hiroshima. This story conveys the awesome power of self-sustaining nuclear reactions. Have you ever thought about applying those ideas to your life? You should.

How We Make Decisions

When was the last time you thought about how you make decisions?

If you're like most people, you've never been explicitly taught how to make effective decisions. You make decisions like a golfer who never took any lessons: miserable with the state of your game and yet not seeking to learn a better swing, and instead hoping for the best every time you lift the club. Hoping that this time your choice will finally work out. In the early 1980s, Charlie Munger and his partner Warren Buffett realized that a Savings & Loan operation they owned, as with the rest of the industry, was doomed to fail miserably due to forces outside of their control. At a time when almost none of their peers were taking action, they changed course dramatically, massively reducing the effect of the bank's failure on the rest of their business holdings. These two men knew they had to act much differently than their peers.

It worked: The S&L industry collapsed, yet Munger and Buffett escaped with barely a scratch. They saved themselves a great deal of stress and financial pain by applying a uniquely effective system of organized common sense. In hindsight, it seems like an obvious good decision; at the time, it seemed odd and unusual.

The lesson for us is that the people making consistently good decisions take advantage of how the world works. That's wisdom.

Real knowledge of the art of decision making, which remains true across time and circumstances, eras and epochs, can help increase the odds that we get what we want and reduce costly mistakes.

While everyone else is guessing, falling into old patterns, blindly following cognitive biases, we can be clear-headed and laser-focused.

That's what Farnam Street is all about.

Here are some examples of applying — or failing to apply — knowledge about how the world really works.

- It doesn't matter how smart you are if you don't realize where things are additive and where they are multiplicative. Nikola Tesla failed to understand Multiplication by Zero when he failed to realize that poor relations with others affected his life. While the Serbian-American was a brilliant inventor, he had difficulty relating to others, which made him difficult to work with. This problem cost him a Nobel Prize and a fortune that today would likely have made him the richest man in the world.
- While we all rely on maps, which are reductions of complexity, to make decisions, they are not always accurate. General George S. Patton Jr. understood that the map is not the territory. When he visited the troops near Coutances, he found them sitting on the side of the road, studying a map. Responding to Patton's inquiry as to

why they had not crossed the Seine, the troops informed him that they were studying the map and could not find a safe place to wade across. Patton informed them that he had just waded across it and it was not more than two feet deep.

- While we all like to be in the sexy industries, that desire shows an under-appreciation for the laws of thermodynamics. Smart companies like Berkshire Hathaway, guided by legendary investor Warren Buffett, understand that contrast is important. Sexy internet businesses are rarely effective, no matter how good they are, because the others are nearly just as good. What you want is contrast — to be the big fish in a small pond. And when you analyze the types of investments he's made over the years, that's what you find. If you're going to compete with people, you want to compete with people who are way less sophisticated than you.
- Understanding and applying the mental model of relativity helped Michael Abrashoff take the worst-performing ship in the US Pacific Fleet and turn it into the best. In his book, *It's Your Ship*, he wrote: "The most important skill a skipper can have is the ability to see through the eyes of the crew."

This website is about understanding and applying these time-tested mental models. Knowing how the world works means that you can stop fighting reality — and yourself along with it.

General Thinking Concepts

Combining intelligent preparation — learning about the big time-tested ideas from multiple disciplines — with general thinking frameworks will dramatically improve your decision-making skills.

These thinking frameworks help you look at problems through different lenses.

- Inversion — Otherwise known as thinking something through in reverse or thinking "backwards," inversion is a problem-solving technique.
- Second-Order Thinking — Ask yourself, "And then what?"
- The Map Is Not the Territory — The map of reality is not reality itself. If any map were to represent its actual territory with perfect fidelity, it would be the size of the territory itself.

All of these concepts (and six others) can be found in *The Great Mental Models Volume 1: General Thinking Concepts*.

51. How Not to Be Stupid

After a four-hour conversation on The Knowledge Project (Part 1, Part 2), Adam Robinson (@IAmAdamRobinson) and I shared another 10-minutes that shouldn't be missed on how not to be stupid.

Shane Parrish: Adam, you did a presentation once on how not to be stupid. Can you tell me about that? What is stupidity?

Adam Robinson: Right. It's so funny you should ask that, because people think stupidity is the opposite of intelligence. In fact, stupidity is the cost of intelligence operating in a complex environment. It's almost inevitable. And so I was asked by an organizer of an investment conference in the Bahamas of some elite global investors to do a talk on anything I wanted to do, except not about investing. It's just, pick an interesting topic. So I thought for a second and I blurt out, "Okay. How about how not to be stupid?" He laughed and he said, "Okay. Great." It took me a month of hard thinking, mind you, just to define stupidity. By the way, if you're in any field and you want to find ways to innovate, focus on words that are commonly used and try to define them simply.

It took me about a month, and I defined stupidity as overlooking or dismissing conspicuously crucial information. Right? It's crucial information, like you better pay attention to it. It's conspicuous, like it's right in front of your nose and yet you either overlook it or you dismiss it. How not to be stupid, what are the causes of human error—and it took me a couple of months of research just to come up with data points, because most stupidity is ignored or swept under the rug. I studied instances of scientific stupidity and literary stupidity and military stupidity and every other kind of stupidity, as well as two domains that engineer stupidity.

One is benign: magic. The magician misdirects your attention. The whole goal of the magician is to make you stupid, to not notice something you should have. The other is frauds and cons and hoaxes. That's also—but that's a malicious, malevolent kind of engineering of stupidity. The magician does so with our full consent, for entertainment purposes. The conman engineers stupidity for their own gain. I do historical research, everything, and I identify seven factors that lead to stupidity.

These seven factors are fascinating. In no particular order: one, being outside your normal environment or changing your routines. Two, being in the presence of a group. Three, being in the presence of an expert or if you, yourself, are an expert. Four, doing any task that requires intense focus. Five, information overload. Six, physical or emotional stress, fatigue. Seven—I'll come back to seven. I forget it right now. It's a few years. It'll come back to me in a second.

All seven factors are present in U.S. hospitals. All seven factors. This will astonish you.

This was recently written about, but I don't think it's really dawned on people. In the United States every year, there are roughly 30,000 fatalities from automobile accidents. That is a benchmark. How many deaths accidentally occur, accidentally, in hospitals every year? In other words, you go in with a broken arm and you don't come out. Not, you died as a result of what you went in for. You died because of error, human error. I would tell you the current best estimate—this is deaths, mind you, not injuries—is 210 to 440 thousand people die every year in the United States from hospital error.

[quote]Stupidity is overlooking or dismissing conspicuously crucial information[/quote]

(Editors note, that was not part of the conversation but will add context: When it comes to overloading our cognitive brains, the seven factors are: being outside of your circle of competence, stress, rushing or urgency, fixation on an outcome, information overload, being in a group where social cohesion comes into play, and being in the presence of an "authority." Acting alone any of these are powerful enough, but together they dramatically increase the odds you are unaware that you've been cognitively compromised.)

We know what to do, we just don't do it correctly. (Atul Gawande and I talk about this in [our interview](#)).

It's the third leading cause of death in the United States, right behind cancer and heart disease. If those seven factors—by the way, you don't need all seven factors to be present. They're additive. Oh, I remember what the final one was, and it's so funny I should forget it because it's the one that usually triggers stupidity. Rushing or a sense of urgency. So funny I would forget that one. It's usually the first one I say. By the way, if you're outside your normal environment and you are rushing, you are in big trouble, which is why often people are rushing on the way to the airport and they forget their passport or they do something. It has to do with information overload. All seven factors were present at the U.S. Challenger disaster. Remember back in 1986?

Didn't have to happen. All seven factors were present. There was the musician Yo-Yo Ma, in 1998 I believe, was rushing to an appointment in New York City. He lives in Boston. He was outside his normal environment, rushing, and he was preoccupied because he was late for an appointment. Three of the seven factors. You don't need all seven to create stupidity. In the back of the cab in which he's being driven is his million-dollar cello in a big blue Plexiglas thing. It's in the trunk. He gets out of the cab, he leaves it in the back of the trunk. All of a sudden, because Yo-Yo Ma is such a celebrity, the mayor is called, the police chief and all cars bulletin goes out, find this cello.

Cello?

They do. In the press conference, get this, he says, "I just did something stupid." I'm using air quotes. That's an exact phrase. "I just did something stupid. I was in a rush." Sure enough, in my research, I found three other situations where world class musicians were in a different city, rushing, and they left their instruments. Each one of them. One a \$3 million violin. He was on a national tour, left a \$3 million violin in an Amtrak train. Imagine \$3 million violin in the luggage compartment of an Amtrak train. Fortunately, they called ahead and they found it at the next station. He was lucky. Each of the musicians, in exactly the same—

Circumstance.

*—circumstances led to stupidity. Now, Atul Gawande wrote a book called [The Checklist Manifesto](#). Atul Gawande is brilliant. Brilliant, brilliant, brilliant. However, the problem with checklists is that the stupidity factors override them. The worst aviation disaster in history, *Shane*, occurred in 1977. Nearly 600 lives were lost when two planes collided during the day on the ground. Imagine, two planes collided in an airport on the ground. Six hundred lives were lost. You might say, how does that even happen? All seven factors were present. Something else. Do you know what the pilot that caused the crash was doing right before he took off and slammed into the plane? He was racing through a checklist.*

Checklists don't help you if you're stupid about the checklist. You're just not going to use it. A really important takeaway from that, and I'm so glad we got that final question in, is beware of rushing—and if these factors are present, don't make any important decisions. It doesn't take much. By the way, I mentioned fatigue and illness. If you're tired or emotionally overwrought, if you have pulled an all-nighter, you have the motor control and the reflex speed of someone who is legally drunk. An all-nighter you think, I mean we've all pulled all-nighters, right? We all sometimes pull multiple all-nighters.

You gotta be aware. You may think that cognitively you're okay, but your motor control skills and your reflexes are those of someone who's legally drunk. You've really got to be careful. By the way, multitasking is information overload. That comes under the information overload thing, and if you're talking on Bluetooth while you're driving a car, you have exponentially increased the odds that you're going to get into an accident.

This is why when you're lost, the first thing you do is turn down the radio.

Oh, fascinating. You're right.

When you're in a car, when you get lost, you always...one of the first things you do is eliminate an input, which is the radio.

That's so funny. You're right.

Or if you're talking with somebody you say, "Hold on a second," because you intuitively know that that's just—subconsciously, you know that's distracting you.

By the way, that's so funny you should mention that, because that's why when I tell people that statistic about...talking on Bluetooth on the phone when you're driving is incredibly dangerous. People say, "Yeah, but what about if someone's in the front of the seat talking to you?" That in fact doubles your odds. If someone's in the front seat with you, talking while you're driving, you've doubled the chances of your getting into an accident. Just doubled. Just that, but the difference is that that person, when you are dealing with unusual traffic conditions, he or she will shut up.

Right, they can see it.

They can see it. The person on the phone who's talking on Bluetooth doesn't shut up. You're still getting the input. That's why it's so dangerous.

That's really interesting. I never thought of that.

Yeah. Well, I didn't think about it until I researched it.

52. The Decision Matrix: How to Prioritize What Matters

The decisions we spend the most time on are rarely the most important ones. Not all decisions need the same process. Sometimes, trying to impose the same process on all decisions leads to difficulty identifying which ones are most important, bogging us down and stressing us out.

I remember once struggling at the intelligence agency shortly after I received a promotion. I was being asked to make too many decisions. I had no way to sort through them to figure out which ones mattered, and which ones were inconsequential.

The situation built slowly over a period of weeks. My employees were scared to make decisions because their previous boss had hung them out to dry when things went wrong. My boss, a political high flyer, also liked to delegate down the riskiest decisions. As a result, I had more decisions to make than capacity to make them. I was working longer and longer to keep up with the volume of decisions. Worse, I followed the same process for all of them. I was focusing on the most urgent decisions as the cost of the most important decisions.

It was clear to me that I wasn't the right person to make all of the decisions. I needed a quick and flexible framework to categorize decisions into the ones I should be making and the ones I should be delegating. I figured most of the urgent decisions could be made by the team because they were easily reversible and not very consequential. In fact, they were only becoming urgent because the team wasn't making the decisions in the first place. And because I was rushing through these decisions in an effort to put more time into the important decisions, I was making worse choices than the team would have.

As I was walking home one night, I came up with an idea that I used from the next day on, with pretty good success. I call it the Decision Matrix. It's a decision making version of the Eisenhower Matrix, which helps you distinguish between what's important and what's urgent. It's so simple you can draw it on a napkin, and once you get it, you get it.

While it won't make the decisions for you, it will help you quickly identify which decisions you should focus on.

The Decision Matrix

My strategy for triaging was simple. I separated decisions into four possibilities based on the type of decision I was making.

1. Irreversible and inconsequential
2. Irreversible and consequential
3. Reversible and inconsequential
4. Reversible and consequential

The great thing about the matrix is that it can help you quickly delegate decisions. You do have to do a bit of mental work before you start, such as defining and communicating consequentiality and reversibility, as well as where the blurring lines are.

The Decision Matrix in Practice

This matrix became a powerful ally to help me manage time and make sure I wasn't bogged down in decisions where I wasn't the best person to decide.

I delegated both types of inconsequential decisions. Inconsequential decisions are the perfect training ground to develop judgment. This saved me a ton of time. Before this people would come to me with decisions that were relatively easy to make, with fairly predictable results. The problem wasn't making the decision—that took seconds in most cases. The problem was the 30 minutes the person spent presenting the decision to me. I saved at least 5–7 hours a week by implementing this one change.

I invested some of that time meeting with the people making these decisions once a week. I wanted to know what types of decisions they made, how they thought about them, and how the results were going. We tracked old decisions as well, so they could see their judgment improving (or not).

Consequential decisions are a different beast. Reversible and consequential decisions are my favorite. These decisions trick you into thinking they are one big important decision. In reality, reversible and consequential decisions are the perfect decisions to run experiments and gather information. The team or individual would decide experiments we were going to run, the results that would indicate we were on the right path, and who would be responsible for execution. They'd present these findings.

Consequential and irreversible decisions are the ones that you really need to focus on. All of the time I saved from using this matrix didn't allow me to sip drinks on the beach.

Rather, I invested it in the most important decisions, the ones I couldn't justify delegating. I also had another rule that proved helpful: unless the decision needed to be made on the spot, as some operational decisions do, I would take a 30-minute walk first.

The key to successfully employing this in practice was to make sure everyone was on same page with the terms of consequential and reversible. At first, people checked with me but later, as the terms became clear, they just started deciding.

While the total volume of decisions we made as a team didn't change, how they were allocated within the team changed. I estimate that I was personally making 75% fewer decisions. But the real kicker was that the quality of all the decisions we made improved dramatically. People started feeling connected to their work again, productivity improved, and sick days (a proxy for how engaged people were) dropped.

Give the Decision Matrix a try—especially if you're bogged down and fighting to manage your time, it may change your working life.

53. The Skill You've Never Been Taught: How to Think Better

No skill is more valuable or harder to come by than the ability to critically think through problems.

Thinking better than others means you'll have more free time and fewer problems. If you can't think well, you'll spend a lot of time fixing avoidable mistakes.

If you stop thinking when most people stop thinking, you'll come to the same conclusions most people come to. Thinking is hard, so it's natural that most people stop as soon as possible. We get the gist of something and move on to the next problem.

Where do the ideas come from? Mine come from sitting and thinking.

Ed Thorp

How can we learn to think better?

One answer comes from the lecture Solitude and Leadership by William Deresiewicz, author of the *New York Times* bestseller *Excellent Sheep: The Miseducation of the American Elite and the Way to a Meaningful Life*. The entire speech, which was delivered at Westpoint, is worth reading, but here is the essential takeaway.

Learning How To Think

Let's start with how you don't learn to think. A study by a team of researchers at Stanford came out a couple of months ago. The investigators wanted to figure out how today's college students were able to multitask so much more effectively than adults. How do they manage to do it, the researchers asked? The answer, they discovered—and this is by no means what they expected—is that they don't. The enhanced cognitive abilities the investigators expected to find, the mental faculties that enable people to multitask effectively, were simply not there. In other words, people do not multitask effectively. And here's the really surprising finding: the more people multitask, the worse they are, not just at other mental abilities, but at multitasking itself.

One thing that made the study different from others is that the researchers didn't test people's cognitive functions while they were multitasking. They separated the subject group into high multitaskers and low multitaskers and used a different set of tests to measure the kinds of cognitive abilities involved in multitasking. They found that in every case the high multitaskers scored worse. They were worse at distinguishing between relevant and irrelevant information and ignoring the latter. In other words, they were more distractible. They were worse at what you might call "mental filing": keeping information in the right conceptual boxes and being able to retrieve it quickly. In other words, their minds were more disorganized. And they were even worse at the very thing that defines multitasking itself: switching between tasks.

Multitasking, in short, is not only not thinking, it impairs your ability to think. Thinking means concentrating on one thing long enough to develop an idea about it. Not learning other people's ideas, or memorizing a body of information, however much those may sometimes be useful. Developing your own ideas. In short, thinking for yourself. You simply cannot do that in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube.

I find for myself that my first thought is never my best thought. My first thought is always someone else's; it's always what I've already heard about the subject, always the conventional wisdom. It's only by concentrating, sticking to the question, being patient, letting all the parts of my mind come into play, that I arrive at an original idea. By giving my brain a chance to make associations, draw connections, take me by surprise. And often even that idea doesn't turn out to be very good. I need time to think about it, too, to make mistakes and recognize them, to make false starts and correct them, to outlast my impulses, to defeat my desire to declare the job done and move on to the next thing.

*I used to have students who bragged to me about how fast they wrote their papers. I would tell them that the great German novelist Thomas Mann said that a writer is someone for whom writing is more difficult than it is for other people. The best writers write much more slowly than everyone else, and the better they are, the slower they write. James Joyce wrote *Ulysses*, the greatest novel of the 20th century, at the rate of about a hundred words a day—half the length of the selection I read you earlier from *Heart of Darkness*—for seven years. T. S. Eliot, one of the greatest poets our country has ever produced, wrote about 150 pages of poetry over the course of his entire 25-year career. That's half a page a month. So it is with any other form of thought. You do your best thinking by slowing down and concentrating.*

Improving Thinking

The best way to improve your thinking ability is to spend time thinking.

Immersing ourselves in a subject and giving it our full attention offers insights that can't be gained simply by skimming on the surface.

How can we force ourselves to spend more time thinking?

One way to engage with an idea is to write about it.

If you're thinking without writing, you only think you're thinking.

Leslie Lamport

While we naturally understand that writing is a good way to share ideas with others, we under-appreciate just how much good writing helps us think about an idea ourselves.

Writing is not only a means of communication, it enables us to practice reasoning.

Writing forces you to slow down, focus, and think deeply. In a world where attention is fragmented into seconds, thinking becomes more reactive than reasoned. Only when take time to play with our ideas can we hope to think about them substantially. Writing requires sticking with something a little longer and developing a deeper understanding.

Writing is the process by which we realize we do not understand and the process by which we come to understand.

Writing requires the compression of an idea. When done poorly, compression removes crucial information. When done well, compression keeps the essential and removes the rest. Compression requires both thinking and clarity, which is one reason writing is an important aid to thinking.

It's only by concentrating, sticking to the question, being patient, letting all the parts of my mind come into play, that I arrive at an original idea. By giving my brain a chance to make associations, draw connections, take me by surprise.

— William Deresiewicz

Good writing gives poor thinking nowhere to hide. It's easy to read and flows. Poor writing is a drag as your mind is forced to sift through the obfuscation to try and pull out the right information. Poor writing is a strong indication of poor thinking.

Good writing requires thinking. Thinking takes time. Good thinking is expensive, but bad thinking costs a fortune.

The Bottom Line

The process of writing helps you think through an idea.

Writing forces you to test your thinking. Strangers can't know your thoughts, unless you put them into words. So one way to test your ideas is to let other people read them.

Take the time to write down your thoughts.

54. The Anatomy of a Decision: An Introduction to Decision Making

“The only proven way to raise your odds of making a good decision is to learn to use a good decision-making process—one that can get you the best solution with a minimal loss of time, energy, money, and composure.”

— John Hammond

This is an introduction to decision making.

A good decision-making process can literally change the world.

Consider the following example from Predictable Surprises: In 1962, when spy planes spotted Soviet missiles in Cuba, U.S. military leaders urged President Kennedy to authorize an immediate attack. Fresh from the bruising failure of the Bay of Pigs, Kennedy instead set up a structured decision-making process to evaluate his options. In a precursor of the Devil's Advocacy method, Kennedy established two groups each including government officials and outside experts, to develop and evaluate the two main options—attack Cuba or set up a blockade to prevent more missiles from reaching its shores. Based on the groups' analysis and debate, Kennedy decided to establish a blockade. The Soviets backed down, and nuclear war was averted. Recently available documents suggest that if the United States had invaded Cuba, the consequences would have been catastrophic: Soviet missiles that had not been located by U.S. Intelligence could still have struck several U.S. cities.

The concept of a decision-making process can be found in the early history of thinking.

Decisions should be the result of rational and deliberate reasoning.

Plato argues that human knowledge can be derived based on reason alone using deduction and self-evident propositions. Aristotle formalized logic with logical proofs where someone could reasonably determine if a conclusion was true or false.

However, as we will discover, not all decisions are perfectly rational. Often, we let our system one thinking—intuition—make decisions for us. Our intuition is based on long-term memory that has been primarily acquired over the years through learning and allows our mind to process and judge without conscious awareness. System one thinking, however, does not always lead to optimal solutions and often tricks our mind to thinking that consequences and second-order effects are either non-existent or less probable than reality would indicate.

In Predictable Surprises Max Bazerman writes:

Rigorous decision analysis combines a systematic assessment of the probabilities of future events with a hard-headed evaluation of the costs and benefits of particular outcomes. As such, it can be an invaluable tool in helping organizations overcome the biases that hinder them in estimating the likelihood of unpleasant events. Decision analysis begins with a clear definition of the decision to be made, followed by an explicit statement of objectives and explicit criteria for assessing the “goodness” of alternative courses of action, by which we mean the net cost or benefit as perceived by the decision-maker. The next steps involve identifying potential courses of action and their consequences. Because these elements often are laid out visually in a decision tree, this technique is known as “decision tree analysis.” Finally, the technique instructs decision-makers to explicitly assess and make trade-offs based on the potential costs and benefits of different courses of action.

To conduct a proper decision analysis, leaders must carefully quantify costs and benefits, their tolerance for accepting risk, and the extent of uncertainty associated with different potential outcomes. These assumptions are inherently subjective, but the process of quantification is nonetheless extremely valuable' it forces participants to express their

assumptions and beliefs, thereby making them transparent and subject to challenge and improvement.

From Judgment in Management Decision Making by Max Bazerman:

The term judgment refers to the cognitive aspects of the decision-making process. To fully understand judgment, we must first identify the components of the decision-making process that require it.

Let's look at six steps you should take, either implicitly or explicitly, when applying a "rational" decision-making process to each scenario.

1. Define the problem. (M)anagers often act without a thorough understanding of the problem to be solved, leading them to solve the wrong problem. Accurate judgment is required to identify and define the problem. Managers often err by (a) defining the problem in terms of a proposed solution, (b) missing a bigger problem, or (c) diagnosing the problem in terms of its symptoms. Your goal should be to solve the problem not just eliminate its temporary symptoms.

2. Identify the criteria. Most decisions require you to accomplish more than one objective. When buying a car, you may want to maximize fuel economy, minimize cost, maximize comfort, and so on. The rational decision maker will identify all relevant criteria in the decision-making process.

3. Weight the criteria. Different criteria will vary in importance to a decision maker. Rational decision makers will know the relative value they place on each of the criteria identified. The value may be specified in dollars, points, or whatever scoring system makes sense.

4. Generate alternatives. The fourth step in the decision-making process requires identification of possible courses of action. Decision makers often spend an inappropriate amount of search time seeking alternatives, thus creating a barrier to effective decision making. An optimal search continues only until the cost of the search outweighs the value of added information.

5. Rate each alternative on each criterion. How well will each of the alternative solutions achieve each of the defined criteria? This is often the most difficult stage of the decision-making process, as it typically requires us to forecast future events. The rational decision maker carefully assesses the potential consequences on each of the identified criteria of selecting each of the alternative solutions.

6. Compute the optimal decision. Ideally, after all of the first five steps have been completed, the process of computing the optimal decision consists of (a) multiplying the ratings in step 5 by the weight of each criterion, (b) adding up the weighted ratings across all of the criteria for each alternative, and (c) choosing the solution with the highest sum of weighted ratings.

Hammond, Keeney, and Raiffa suggest 8 steps in their book Smart Choices:

- 1. Work on the right problem.*
- 2. Identify all criteria.*
- 3. Create imaginative alternatives.*
- 4. Understand the consequences.*
- 5. Grapple with your tradeoffs.*
- 6. Clarify your uncertainties.*
- 7. Think hard about your risk tolerance.*
- 8. Consider linked decisions.*

* * *

People, however, are not always entirely logical machines. In Judgment in Managerial Decision Making, the distinction between System One and System Two thinking becomes clear:

System 1 thinking refers to our intuitive system, which is typically fast, automatic, effortless, implicit, and emotional. We make most decisions in life using System 1 thinking. For instance, we usually decide how to interpret verbal language or visual information

automatically and unconsciously. By contrast, System 2 refers to reasoning that is slower, conscious, effortful, explicit, and logical. System 2 thinking can be broken down into (1) define the problem; (2) identify the criteria; (3) weigh the criteria; (4) generate alternatives; (5) rate each alternative on each criterion; (6) compute the optimal decision. In most situations, our system 1 thinking is quite sufficient; it would be impractical, for example, to logically reason through every choice we make while shopping for groceries. But System 2 logic should preferably influence our most important decisions.

* * *

When making a decision, we are psychologically influenced either consciously or unconsciously. By exploring these biases and other elementary, worldly wisdom, we hope to make you a better decision-maker.

Following a rational decision process can help us focus on outcomes that are low in probability but high in potential costs. Without easily quantifiable costs, we often dismiss low probability events or fall prey to biases. We don't want to be the fragilista.

Even rational decision-making processes like the one presented above make several assumptions. The first assumption is that a rational decision-maker is completely informed which means they know about all the possible options and outcomes. The second major assumption is that the decision-maker does not fall prey to any biases that might impact the rational decision.

In researching decision-making processes, it struck us as odd that few people question the information upon which criteria are measured. For instance, if you are purchasing a car and use fuel efficiency as the sole criterion for decision making, you would need to make sure that the cars under consideration were all tested and measured fuel consumption in the same way. This second order of thinking can help you make better decisions.

If you want to make better decisions, you should read Judgment in Managerial Decision Making. That is the best book I've come across on decision making. If you know of a better one, please send me an email.

Stanovich's book, What Intelligence Tests Miss: The Psychology of Rational Thought, proposes a whole range of cognitive abilities and dispositions independent of intelligence that have at least as much to do with whether we think and behave rationally.

55. Creating a Decision Journal: Template And Example Included

We all make decisions. And yet few of us think about what we can learn from our past decisions to make smarter decisions in the future. A decision journal helps you learn from past decisions, think through current decisions, and avoid problems before they happen. In this article we'll cover:

- Your Product is Decisions
- What is a Decision Journal
- A Decision Journal Template
- An Example Decision
- Tips on Using a Decision Journal

Ok, let's dig in.

Your Product is Decisions

In most organizations your product is decisions. By and large, your success will be the sum of the decisions you make over your career. The problem is it's not easy to get better at making decisions.

Bosses would be the easy solution to helping you improve. After all, they have the best view of the problem and you. They should be able to point out strengths and weaknesses in your decision process as well as your judgment. All of this is known at the time you made the decision. This is hard and subjective and requires people doing a lot of thinking. So bosses tend to default to resulting, a process by which the outcome of the decision is attached to the process used to make that decision. Under resulting good outcomes are the product of good decisions and bad outcomes are the product of bad decisions. The problem isn't that people don't want to get better at decisions, it's the system that's preventing them from doing so.

Even if we can't get our boss to help us make better decisions we can take things into our own hands. The way to test the quality of your decisions is to test the process by which you make them. Daniel Kahneman, Nobel Prize winner and dean of biases, argues that using a decision journal is the best solution. Kahneman said:

Go down to a local drugstore and buy a very cheap notebook and start keeping track of your decisions. And the specific idea is whenever you're making a consequential decision, something going in or out of the portfolio, just take a moment to think, write down what you expect to happen, why you expect it to happen and then actually, and this is optional, but probably a great idea, is write down how you feel about the situation, both physically and even emotionally. Just, how do you feel? I feel tired. I feel good, or this stock is really draining me. Whatever you think.

The key to doing this is that it prevents something called hindsight bias, which is no matter what happens in the world, we tend to look back on our decision-making process, and we tilt it in a way that looks more favorable to us, right? So we have a bias to explain what has happened.

A decision journal helps you collect accurate and honest feedback on what you were thinking at the time you made the decision. This feedback helps you see when you were stupid and lucky as well as when you were smart and unlucky. Finally, you can get the feedback you need to make better decisions.

The key to understanding the limits to our knowledge (see circle of competence) is to check the results of our decisions against what we thought was going to happen and why we thought it was going to happen. That feedback loop is incredibly powerful because our minds won't provide it by themselves.

I'll give you the spoiler right now. We don't know as much as we think we know. We're fooled into thinking that we understand something when we don't and we have no means to correct ourselves.

Our minds revise history to preserve our view of ourselves. The story that we tell ourselves conflates the cause and effect of a decision we made and the actual outcome. The best cure for this revising is the decision journal.

What is a Decision Journal?

You can think of a decision journal as quality control for our thinking — something like what we'd find in a manufacturing plant or a restaurant. Using a decision journal is simple but not easy. Implementing one requires discipline and humility.

Not all decisions need to be journaled. Decisions of consequence should be logged with the basics of the situation, what you expect to happen, and why.

You should write in your decision journal before you make the decision official. Writing is the process where you realize that you don't know what you think you know. Writing about your decision forces you to explain your thinking. If we write about the decision after we make it, it's often too late to do anything about it.

Write your decision down sleep on it and read it with fresh eyes in the morning. Often you'll find that what you wrote doesn't make sense. Catching mistakes before you make a decision saves you time and money.

A Decision Journal Template

The key question is what information to include in your decision journal. Here's the template we use at FS.

Decision No: _____

Date: _____

Time: _____

Decision: _____

Mental/Physical State (check boxes)

Energized ☐ Focused ☐ Relaxed ☐

Confident ☐ Tired ☐ Accepting ☐

Accommodating ☐ Anxious ☐ Resigned ☐

Frustrated ☐ Angry ☐

The situation/context:

The problem statement or frame:

The variables that govern the situation include:

[Click for PDF](#)

Whenever you're making a consequential decision, either individually or as part of a group, you take a moment and write down:

1. The situation or context
2. The problem statement or frame
3. The variables that govern the situation
4. The complications or complexity as you see it
5. Alternatives that were seriously considered and why they were not chosen (think: the work required to have an opinion)
6. A paragraph explaining the range of outcomes
7. A paragraph explaining what you expect to happen and the reasoning and actual probabilities you assign to each projected outcome (The degree of confidence matters, a lot.)

8. The time of day you're making the decision and how you feel physically and mentally (If you're tired, for example, write it down.)

You have to make this part your own. I've seen others include:

- What's the primary thesis
- What is the expected outcome(s)
- What are the second and third-order consequences
- What is the worst-case scenario and why that's ok
- What is the potential upside beyond the core thesis
- What emotions am I experiencing
- What is the opportunity cost (by doing this what am I not doing)
- What unique advantages or insights do I have in this situation
- Who is the best person to make this decision
- What does this look like in 5 weeks, 5 months, 5 years?

An Example Decision

Perhaps an example will help illustrate. Here's a real decision that I made using the FS decision journal template.

Tips on Using a Decision Journal

Here are some tips to keep in mind as you implement your decision journal.

Your decision journal can be tailored to the situation and context. Specific decisions might include trade-offs, second-order effects, weighting criteria, or other relevant factors. These examples are only to get you started.

We can't improve our thinking if we can't see it. Don't spend too much time on the brief and obvious insights. Often our first thoughts represent the thinking of someone else and not our own thinking.

Any decision you're journaling is inherently complex and may involve non-linear systems. In such a world, small effects can cause disproportionate responses whereas bigger ones might have no impact. Remember that causality is complex, especially in complex domains.

Two common ways people wiggle out of their own decisions are hindsight bias and jargon. It's hard to remember what we knew at the time and what we were thinking. Hindsight makes things far more explainable and changes our story. A decision journal helps combat this by recording what you knew and what you thought at the time. When you look at your own handwriting you come face to face with the person you were when you made the decision. There is nowhere to hide.

The words we use are also important. When we use vague terms, we give ourselves wiggle room. If we want to get better at making decisions we can't give ourselves wiggle room. Be clear. Be direct. Be simple. An 8-year-old should understand what decision you're making and why.

A decision journal that sits on the shelf is less useful than one that gets reviewed. Every six months or so pick it up and look at your past decisions, update entries with what actually happened, and spend time thinking about your process.

Realizing where you make mistakes, how you make them, what types of decisions you're bad at, etc., helps you make better decisions going forward. When you start to identify patterns, you can change your decision process to help account for the things you miss. Just because you had a bad outcome doesn't mean you made a bad decision. You might have made the right decision (which, in our sense, means that used a good process) and still had a bad outcome. We call that a bad break.

When you use a decision journal, you'll discover two things right away. First, you're right a lot of the time. Second, it's often for the wrong reasons. Discovering how lucky you are can be somewhat humbling. This is where the learning begins.

56. Swing for Success: Mastering Your Circle of Competence with Ted Williams' Winning Strategy

Ted Williams (1918-2002) was arguably the greatest hitter in baseball history. He was the last player to break the revered .400 barrier—a remarkable achievement in any era.

How did he do it, and what can we learn from him to improve our decision-making?

Admittedly, I'm not a diehard baseball fan, but Ted Williams' book, *The Science of Hitting*, piqued my interest. It contains a compelling illustration of him at-bat, with the strike zone divided into 77 distinct squares.

Source: The Science of Hitting

Williams recognized that waiting for a pitch in his sweet spot significantly increased his chances of getting a hit. Being patient and waiting for the right opportunity, offered a 40% hit rate. Impatience, on the other hand, could lower his success rate to a mere 23-25%. Williams understood that average batters turned into great batters if they waited for the right pitch, and even the best batters turned into average ones if they swung at the wrong pitch.

A good hitter can hit a pitch that is over the plate three times better than a great hitter with a questionable ball in a tough spot.

According to baseball legend Rogers Hornsby, the most crucial factor for a hitter is getting a good ball to hit. Williams took this advice to heart, meticulously dividing the strike zone into 77 baseball-sized spaces, and understanding which pitches yielded the highest odds of success for him.

The Zone of Opportunity

We all possess a zone of opportunity, where the odds are in our favor. This is your Circle of Competence, your “sweet spot.”

The most important thing about your circle of competence is knowing where it starts and stops. While simple, it's not easy. As Richard Feynman once said, “the first principle is that you must not fool yourself, and you are the easiest person to fool.”

A common mistake is to confuse familiarity with understanding. Deep fluency takes a lot of work. If you want to test your understanding of something (or learn something new), try this approach.

“It's not a competency if you don't know the edge of it.”

— Charlie Munger

Warren Buffett understands sticking to what you understand rather than chasing what's new and exciting. He writes:

If we have a strength, it is in recognizing when we are well within our circle of competence and when we are approaching the perimeter. Predicting the long term economics of companies that operate in fast-changing industries is simply far beyond our perimeter. If others claim predictive skills in those industries—and seem to have claims validated by the behaviour of the stock market we neither envy nor emulate them. Instead, we just stick with what we understand. If we stray, we will have done so inadvertently, not because we got restless and substituted hope for rationality.

Unlike Williams, Buffett can't be called “out” on strikes if he resists pitches that are barely in the strike zone. He can, quite literally, wait for the perfect pitch—looking at thousands of different investments before finding one that is just right.

If straying from our core competence decreases our success rate, what can we do to improve our odds?

When you are operating outside of your area of understanding, focusing on positioning rather than predicting is crucial. Two ways to achieve this are by increasing the margin of safety and ensuring circumstances don't force us into a bad decision.

By learning from Ted Williams and understanding our Circle of Competence, we can make better decisions and increase our odds of success in various domains.

57. This Time is Different: The Four Most Costly Words Ever Spoken

When we look at situations we're always looking for what's unique. We should, however, give more thought to similarities.

"This time is different" could be the 4 most costly words ever spoken. It's not the words that are costly so much as the conclusions they encourage us to draw.

We incorrectly think that differences are more valuable than similarities.

After all, anyone can see what's the same but it takes true insight to see what's different, right? We're all so busy trying to find differences that we forget to pay attention to what is the same.

Imagine sitting in a meeting where people are about to make the same mistake they made last year on the same decision. Let's say, for example, Jack has a history of messing up the annual tax returns. He's a good guy. He's nice to everyone. In fact, he buys everyone awesome Christmas presents. But the last three years—the period he's been in charge of tax returns—have been nothing short of a disaster causing more work for you and your department.

The assignment for the tax return comes up and Jack is once again nominated.

Before you have a chance to voice your concerns, one of your co-workers speaks up: "I know Jack has dropped the ball on this assignment in the past but I think this time is different. He's been working hard to make sure he's better organized."

That's all it takes. Conversation over — everyone is focused on what's unique about this time and it's unlikely, despite ample evidence, that you'll be able to convince them otherwise.

In part, people want to believe in Jack because he's a nice guy. In part, we're all focused on why this time is different and we'll ignore evidence to the contrary.

Focusing on what's different makes it easy to forget historical context. We lose touch with the base rate. We only see the evidence that supports our view (confirmation bias). We become optimistic and overconfident.

History provides context. And what history shows us is that no matter how unique things are today there are a lot of similarities with the past.

Consider investors and the dotcom bubble. Collectively people saw this as unprecedented and unique, a massive transformation that was unparalleled.

That reasoning, combined with a blindness to what was the same about this situation and previous ones, encouraged us to draw conclusions that proved costly. We reasoned that everything would change and everyone who owned internet companies would prosper and the old non-internet companies would quickly go into bankruptcy.

All of a sudden profits didn't matter. Nor did revenue. They would come in time, we hoped. Market share mattered no matter how costly it was to acquire.

More than that, if you didn't buy now you'd miss out. These companies would take over the world and you'd be left out.

We got so caught up in what was different that we forgot to see what was the same.

And there were historical parallels: Automobiles, Radio, Television, and Airplanes to name a few. At the time these innovations completely transformed the world as well. You can consider them the dotcoms of yesteryear.

And how did these massively transformational industries end up for investors?

At one time there were allegedly over 70 different auto manufacturing operations in the United States. Only 3 of them survived (and a few of those even required government funds.)

If you catch yourself reasoning based on "this time is different" remember that you are probably speculating. While you may be right, odds are, this time is not different. You just haven't looked for the similarities.

58. Blog Posts, Book Reviews, and Abstracts: On Shallowness

We're quite glad that you read Farnam Street, and we hope we're always offering you a massive amount of value. (If not, email us and tell us what we can do more effectively.) But there's a message all of our readers should appreciate: Blog posts are not enough to generate the deep fluency you need to truly understand or get better at something. We offer a starting point, not an end point.

This goes just as well for book reviews, abstracts, cliff's notes, and a good deal of short-form journalism.

This is a hard message for some who want a shortcut. They want the "gist" and the "high level takeaways", without doing the work or eating any of the broccoli. They think that's all it takes: Check out a 5-minute read, and instantly their decision making and understanding of the world will improve right-quick. Most blogs, of course, encourage this kind of shallowness. Because it makes you feel that the whole thing is pretty easy.

Here's the problem: The world is more complex than that. It doesn't actually work this way. The nuanced detail behind every "high level takeaway" gives you the context needed to use it in the real world. The exceptions, the edge cases, and the contradictions.

Let me give you an example.

A high-level takeaway from reading Kahneman's Thinking Fast, and Slow would be that we are subject to something he and Amos Tversky call the Representativeness Heuristic. We create models of things in our head, and then fit our real-world experiences to the model, often over-fitting drastically. A very useful idea.

However, that's not enough. There are so many follow-up questions. Where do we make the most mistakes? Why does our mind create these models? Where is this generally useful? What are the nuanced examples of where this tendency fails us? And so on. Just knowing about the Heuristic, knowing that it exists, won't perform any work for you.

Or take the rise of human species as laid out by Yuval Harari. It's great to post on his theory; how myths laid the foundation for our success, how "natural" is probably a useless concept the way it's typically used, and how biology is the great enabler.

But Harari's book itself contains the relevant detail that fleshes all of this out. And further, his bibliography is full of resources that demand your attention to get even more backup. How did he develop that idea? You have to look to find out.

Why do all this? Because without the massive, relevant detail, your mind is built on a house of cards.

What Farnam Street and a lot of other great resources give you is something like a brief map of the territory.

Welcome to Colonial Williamsburg! Check out the re-enactors, the museum, and the theatre. Over there is the Revolutionary City. Gettysburg is 4 hours north. Washington D.C. is closer to 2.5 hours.

Great – now you have a lay of the land. Time to dig in and actually learn about the American Revolution. (This book is awesome, if you actually want to do that.)

Going back to Kahneman, one of his and Tversky's great findings was the concept of the Availability Heuristic. Basically, the mind operates on what it has close at hand.

As Kahneman puts it, "An essential design feature of the associative machine is that it represents only activated ideas. Information that is not retrieved (even unconsciously) from memory might as well not exist. System 1 excels at constructing the best possible story that incorporates ideas currently activated, but it does not (cannot) allow for information it does not have."

That means that in the moment of decision making, when you're thinking hard on some complex problem you face, it's unlikely that your mind is working all that successfully without the details. It doesn't have anything to draw on. It'd be like a chess player who

read a book about great chess players, but who hadn't actually studied all of their moves. Not very effective.

The great difficulty, of course, is that we lack the time to dig deep into everything. Opportunity costs and trade-offs are quite real.

That's why you must develop excellent filters. What's worth learning this deeply? We think it's the first-principle style mental models. The great ideas from physical systems, biological systems, and human systems. The new-new thing you're studying is probably either A. Wrong or B. Built on one of those great ideas anyways. Farnam Street, in a way, is just a giant filtering mechanism to get you started down the hill.

But don't stop there. Don't stop at the starting line. Resolve to increase your depth and stop thinking you can have it all in 5 minutes or less. Use our stuff, and whoever else's stuff you like, as an entrée to the real thing.

59. Three Filters Needed to Think Through Problems

One of the best parts of Garrett Hardin's wonderful *Filters Against Folly* is when he explores the three filters that help us interpret reality.

No matter how much we'd like it to, the world does not only operate in our circle of competence. Thus we must learn ways to distinguish reality in areas where we lack even so much as a map.

Most geniuses—especially those who lead others—prosper not by deconstructing intricate complexities but by exploiting unrecognized simplicities.

Andy Benoit

Mental Tools

We need not be a genius in every area but we should understand the big ideas of most disciplines and try to avoid fooling ourselves. That's the core to the mental models approach. When you're not an expert in a field, often the best approach is one that avoids stupidity. There are few better ways of avoiding stupidity than understanding how the world works.

We can never merely do one thing.

Hardin begins by outlining his goal: to understand reality and understand human nature as it really is, removing premature judgment from the analysis.

He appropriately quotes Spinoza, who laid out his principles for political science thusly:

That I might investigate the subject matter of this science with the same freedom of spirit we generally use in mathematics, I have labored carefully not to mock, lament, or execrate human actions, but to understand them; and to this end I have looked upon passions such as love, hatred, anger, envy, ambition, pity, and other perturbations of the mind, not in the light of vices of human nature, but as properties just as pertinent to it as are heat, cold, storm, thunder, and the like to the nature of the atmosphere.

The goal of these mental filters is to understand reality by improving our ability to judge the statements of experts, promoters, and persuaders of all kinds. As the saying goes, we are all laymen in some field.

Hardin writes:

What follows is one man's attempt to show that there is more wisdom among the laity than is generally concluded, and that there are some rather simple methods of checking on the validity of the statements of experts.

1. The Literate Filter

The first filter through which we must interpret reality, says Hardin, is the literate filter: What do the words really mean? The key to remember is that Language is action. Language is not just a way to communicate or interpret; language acts as a call to, or just as importantly, an inhibitor to action.

The first step is to try to understand what is really being said. What do the words and the labels actually *mean*? If a politician proposes a “Poverty Assistance Plan,” that sounds almost inarguably good, no? Many a pork-barrel program has passed based on such labels alone.

But when you examine the rhetoric, you must ask what those words are trying to do: Promote understanding, or inhibit it? If the program had a rational method of assistance to the deserving poor, the label might be appropriate. If it was simply a way to reward undeserving people in his or her district for their vote, the label might be simply a way to fool. *The literate filter asks if we understand the true intent behind the words.*

In a chapter called “*The Sins of the Literate*,” Hardin discusses the misuse of language by examining literate, but innumerate, concepts like “indefinite” or “infinite”:

He who introduces the words “infinity” or any of its derivatives (“forever” or “never” for instance) is also trying to escape discussion. Unfortunately he does not honestly admit the operational meaning of the high-flown language used to close off discussion. “Non-negotiable” is a dated term, no longer in common use, but “infinity” endures forever.

Like old man Proteus of Greek mythology, the wish to escape debate disguises itself under a multitude of verbal forms: infinity, non-negotiable, never, forever, irresistible, immovable, indubitable, and the recent variant “not meaningfully finite.” All these words have the effect of moving discussion out of the numerate realm, where it belongs, and into a wasteland of pure literacy, where counting and measuring are repudiated.

Later, in the final chapter, Hardin repeats:

The talent for handling words is called “eloquence.” Talent is always desirable, but the talent may have an unfair, even dangerous, advantage over those with less talent. More than a century ago Ralph Waldo Emerson said, “The curse of this country is eloquent men.” The curse can be minimized by using words themselves to point out the danger of words. One of their functions is to act as inhibitors of thought. People need to be made allergic to such thought-stoppers as infinity, sacred, and absolute. The real world is a world

of quantified entities: “infinity” and its like are no words for quantities but utterances used to divert attention from quantities and limits.

It is not just innumerate exaggeration we are guarding against, but the literate tendency to replace actors with abstractions, as Hardin calls it. He uses the example of donating money to a poor country (Country X), which on its face sounds noble:

Country X, which is an abstraction, cannot act. Those who act in its name are rich and powerful people. Human nature being what it is, we can be sure that these people will not voluntarily do anything to diminish either their power or their riches...

Not uncommonly, the major part of large quantities of food sent in haste to a poor country in the tropics rot on the docks or is eaten up by rats before it can be moved to the people who need it. The wastage is seldom adequately reported back to the sending country... (remember), those who gain personally from the shipping of food to poor nations gain whether fungi, rats, or people eat the food.

2. The Numerate Filter

Hardin is clear on his approach to numerical fluency: The ability to count, weigh, and compare values in a general or specific way is essential to understanding the claims of experts or assessing any problem rationally:

The numerate temperament is one that habitually looks for approximate dimensions, ratios, proportions, and rates of change in trying to grasp what is going on in the world.

Given effective education—a rare commodity, of course—a numerate orientation is probably within the reach of most people.

[...]

Just as “literacy” is used here to mean more than merely reading and writing, so also will “numeracy” be used to mean more than measuring and counting. Examination of the origins of the sciences shows that many major discoveries were made with very little measuring and counting. The attitude science requires of its practitioners is respect, bordering on reverence, for ratios, proportions, and rates of change.

Rough and ready back-of-the-envelope calculations are often sufficient to reveal the outline of a new and important scientific discovery....In truth, the essence of many of the major insights of science can be grasped with no more than child’s ability to measure, count, and calculate.

*

To explain the use of the literate and numerate filters together, Hardin uses the example of the Delaney Amendment, passed in 1958 to restrict food additives. This example should be familiar to us today:

Concerned with the growing evidence that many otherwise useful substances can cause cancer, Congress decreed that henceforth, whenever a chemical at any concentration was found to cause cancer—in any fraction of any species of animal—that substance must be totally banned as an additive to human food.

From a literate standpoint, this sounds logical. The Amendment sought to eradicate harmful food additives that the free market had allowed to surface. However, says Hardin:

The Delaney Amendment is a monument to innumerate thought. “Safe” and “unsafe” are literate distinctions; nature is numerate. Everything is dangerous at some level. Even molecular oxygen, essential to human life, becomes lethal as the concentration approaches 100 percent.

[...]

Sensitivity is ordinarily expressed as “1 part per X,” where X is a large number. If a substance probably increases the incidence of cancer at a concentration of 1 part per 10,000, one should probably ban it at that concentration in food, and perhaps at 1 in 100,000. But what about 1 part per million?...In theory there is no final limit to sensitivity. What about 1 milligram per tank car? Or 1 milligram per terrestrial globe?

Obviously, some numerical limits must be applied. This is the usefulness of the numerate filter. As Charlie Munger says, "Quantify, always quantify."

3. The Ecology Filter

Hardin introduces his final filter by requiring that we ask the question "*And then what?*"

There is perhaps no better question to prompt second-order thinking.

Even if we understand what is truly being said and have quantified the effects of a proposed policy or solution, it is imperative that we consider the second layer of effects or beyond. Hardin recognizes that this opens the door for potentially unlimited paralysis (the poorly understood and innumerate Butterfly Effect), which he boxes in by introducing his own version of the First Law of Ecology:

We can never merely do one thing.

This is to say, all proposed solutions and interventions will have a multitude of effects, and we must try our best to consider them in their totality. Most unintended consequences are just unanticipated consequences.

In proposing this filter, Hardin is very careful to guard against the *Slippery Slope* argument or the idea that one step in the wrong direction will lead us directly to Hell. This, he says, is a purely literate but wholly innumerate approach to thinking.

Those who take the wedge (Slippery Slope) argument with the utmost seriousness act as though they think human beings are completely devoid of practical judgment. Countless examples from everyday life show the pessimists are wrong...If we took the wedge argument seriously, we would pass a law forbidding all vehicles to travel at any speed greater than zero. That would be an easy way out of the moral problem. But we pass no such law.

In reality, the ecology filter helps us understand the layers of unintended consequences.

Take inflation:

The consequences of hyperinflation beautifully illustrate the meaning of the First Law of Ecology. A government that is unwilling or unable to stop the escalation of inflation does more than merely change the price of things; it turns loose a cascade of consequences the effects of which reach far into the future.

Prudent citizens who have saved their money in bank accounts and government bonds are ruined. In times of inflation people spend wildly with little care for value, because the choice and price of an object are less important than that one put his money into material things. Fatalism takes over as society sinks down into a culture of poverty....

In the end, the filters must be used wisely together. They are ways to understand reality, and cannot be divorced from one another. Hardin's general approach to thinking sums up much like his multi-disciplinary friend Munger's:

No single filter is sufficient for reaching a reliable decision, so invidious comparisons between the three is not called for. The well-educated person uses all of them.

60. How People Make Big Decisions

We all go through psychological steps when we make big decisions. Some people call this the “existential cycle,” which really has four stages: doing, contemplating, preparing, and experimenting.

Echoing Tolstoy on regret avoidance, Sebastian Bailey and Octavius Black write in Mind Gym: Achieve More by Thinking Differently:

These four stages are much like exercises in risk management. No one wants to look back on his or her life at some point and say I wish I would have or If only I had.

While there are other ways, the existential cycle helps us make life changing decisions — like who to marry, where to work, and where to live.

The first stage, “doing,” is where you spend most of your life: It is your settled, equilibrium position. The doing may be all sorts of things— writing emails, riding horses, reading books, washing up, going to meetings, listening to lectures, cooking, dancing, running, sharing stories with friends, telling jokes, or making love. Of course, these are not done all at the same time (not unless you’re really talented). Whatever the activity may be, and however enjoyable or dull it is, you are doing it and it tends to keep you occupied.

Sometimes we get to “contemplating,” where we consider whether or how things would be different. What would life be like if you move to California? (Hint: It won’t make you happier.)

Then occasionally we move to “preparing.”

You search on the web for real estate agents in San Diego or Key West, find out what property prices are, check weather patterns, possibly even visit your preferred destination on your next vacation. You have moved beyond imagining how things could be different to investigating the practical options for how to make them different.

Finally you make the change.

You leave your job, buy a house, and move all your possessions. This stage is called “experimenting.” After you’ve settled in and started the beachside bar you’d dreamed about, this becomes your normal way of living, and you are once again in a state of doing. The process isn’t overly complicated or hard. The challenge becomes moving through it at the right pace in a way that aligns with your principles.

The Doing Magnet

As you travel around your cycle, you will have conversations with yourself that stop you from moving on to the next stage and instead take you back to doing.

Sometimes these thoughts can be very sensible and prevent you from wasting time or following the wrong path. But sometimes, unfortunately, they prevent you from both spotting and taking opportunities that could dramatically improve your life. The trick lies in recognizing the internal conversations and being able to make an informed decision about whether to listen to them or to ignore them and move on.

When the Doing Magnet is Weak

Irrational exuberance are those people who are forever saying things like I wish I hadn't rushed into that or If only I'd thought about it first. Rather than never crossing the Rubicon, they're happy to head over far too easily— without ever considering the size of the army on the other side. In terms of the existential cycle, their doing magnet is relatively weak—the centrifugal momentum of the next new thing is stronger than the gravitational force of the status quo.

If you find that you can't hold down a job, you can't keep a relationship, you spend money on a whim, or you haven't gotten around to making your home into a place you like living in, and you regret it, then you may be suffering from a form of irrational exuberance. The best advice in this situation is this: spend longer at the preparing stage before wading across your Rubicon.

For example, consider one of these choices:

- Think through all the possible disadvantages of taking this course of action as well as the advantages— really make an effort to present the case for caution on this occasion.*
- Contrast the allure of the new situation with how your existing life might improve even if you don't make this big change. People who are always moving on to new jobs often fail to consider how their current jobs could get better. A new job may be attractive, but it is wrong to assume the old one will stay the same. New possibilities could open up. What happens when your boss moves on?*
- Contemplate the bigger and better gains and pleasures you could have if you didn't always go for instant gratification. Could the gratification get more gratifying?*
- Consider any decisions you made in the past that led to situations you later regretted. What can you learn from these that will help you make a wiser decision this time.*

If you Want to Improve, you have to Cross the Rubicon

“Do. Or do not. There is no try.” — Yoda

You have a choice in how you run your life. There is no “can't,” only “will” and “won't.” The trick is knowing why you are, or aren't, moving around the existential cycle and, in particular, crossing your Rubicon. Like we've said, the right thing isn't to always cross or always not cross. The right thing is to understand why you want to cross or don't want to cross, and then make your decision.

Nevertheless, none of us want to live our lives in a constant state of doing. I might not be in good enough shape today to swim 2.4 miles, but that doesn't mean I won't be in the future. Plus, our reasons for remaining in one state may not be strong. At some point, in certain aspects of our lives, if we want to progress, we must cross the Rubicon.

A decision to not cross the Rubicon based on the wrong reasons— when catastrophic fantasies rule our mind-sets— is what causes people to look back on their lives and think If

only. ... All of us who have looked back and been proud of what we have done have crossed the Rubicon at least once and maybe many times.

There's a famous Latin maxim, carpe diem, which translated means "seize the day." The question you have to ask yourself is, When it comes to crossing Rubicons, just how much of a Caesar am I prepared to be?

61. The Two Types of Knowledge: The Max Planck/Chauffeur Test

Charlie Munger, the billionaire business partner of Warren Buffett, frequently tells the story below to illustrate how to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

At the 2007 Commencement to the USC Law School, Munger explained it this way:

I frequently tell the apocryphal story about how Max Planck, after he won the Nobel Prize, went around Germany giving the same standard lecture on the new quantum mechanics. Over time, his chauffeur memorized the lecture and said, "Would you mind, Professor Planck, because it's so boring to stay in our routine. [What if] I gave the lecture in Munich and you just sat in front wearing my chauffeur's hat?" Planck said, "Why not?" And the chauffeur got up and gave this long lecture on quantum mechanics. After which a physics professor stood up and asked a perfectly ghastly question. The speaker said, "Well I'm surprised that in an advanced city like Munich I get such an elementary question. I'm going to ask my chauffeur to reply."

The point of the story is not the quick-wittedness of the protagonist, but rather — to echo Richard Feynman — it's about making a distinction between knowing the name of something and knowing something.

Two Types of Knowledge

The first type of knowledge is real. It can't be bought. It can't be copied. If you want real knowledge you need to earn it. The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work.

Munger continues:

In this world we have two kinds of knowledge. One is Planck knowledge, the people who really know. They've paid the dues, they have the aptitude. And then we've got chauffeur knowledge. They've learned the talk. They may have a big head of hair, they may have fine temper in the voice, they'll make a hell of an impression.

But in the end, all they have is chauffeur knowledge. I think I've just described practically every politician in the United States.

And you are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge.

And there are huge forces working against you. My generation has failed you a bit... but you wouldn't like it to be too easy now would you?

Real knowledge comes when people do the work. On the other hand, we have the people who don't do the work — they pretend. While they've learned to put on a good show, they lack understanding. They can't answer questions that don't rely on memorization. They can't explain things without using jargon or vague terms. They have no idea how things interact. They can't predict the consequences.

"Any fool can know. The point is to understand."

— Albert Einstein

The problem is that it's difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.

In The Art of Thinking Clearly, Rolf Dobelli offers some commentary on distinguishing fake from real knowledge:

With journalists, it is more difficult. Some have acquired true knowledge. Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the

tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and — often as compensation for their patchy knowledge— snarky and self-satisfied in tone. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case.

One way to guard against this is to understand your circle of competence.

Dobelli concludes with some advice worth taking to heart.

Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

62. Avoiding Stupidity is Easier than Seeking Brilliance

The path to victory is to avoid obvious stupidity. It can be hard to appreciate that the person who avoids losing wins. Winning can happen without explicitly seeking to win. The word stupidity is important here. Avoiding stupidity is not an argument to do nothing. Avoiding stupidity is about remembering the obvious, playing in domains where you have an edge, ensuring you are compensated for the risks you take, ensuring you financially and psychologically stay in the game, and having a lot of patience.

The key to avoiding stupidity boils down to knowing which game you are playing. There are two.

Winning or Losing?

Let us explore the difference between a professional game and an amateur game.

Often we focus on trying to be brilliant when we would get a lot more mileage out of avoiding stupidity.

We often focus on trying to be brilliant, yet many great people get far more mileage out of avoiding making stupid mistakes. Amateurs win the game when their opponent loses points, experts win the game by gaining points.

It is remarkable how much long-term advantage people like us have gotten by trying to be consistently not stupid, instead of trying to be very intelligent.

Charlie Munger

Scientist and statistician Simon Ramo wrote a fascinating little book that few people have ever bothered to read called *Extraordinary Tennis Ordinary Players*.

In the book, Ramo identifies the crucial difference between a *Winner's Game* and a *Loser's Game*.

Professionals win points. Amateurs lose them.

Professionals play a winner's game – they win by being better than their opponent. The outcome is mostly within their control.

In a professional game, each player, nearly equal in skill, plays a nearly perfect game rallying back and forth until one player hits the ball just beyond the reach of his opponent. This is about positioning, control, and spin. It's a game of inches and sometimes centimeters. This is not how amateurs play.

In expert tennis, about 80 per cent of the points are won; in amateur tennis, about 80 per cent of the points are lost. In other words, professional tennis is a Winner's Game – the final outcome is determined by the activities of the winner – and amateur tennis is a Loser's Game – the final outcome is determined by the activities of the loser. The two games are, in their fundamental characteristic, not at all the same. They are opposites.

Amateur games are different. Amateur tennis — likely the level you and I play at — is a loser's game. The winner is the person who makes the fewest mistakes and lets the other person beat themselves. If you keep the ball in play long enough, your opponent will make a mistake. In effect, amateurs win because their opponent makes more mistakes than they do.

Ordinary people win at games they are not skilled in by letting their opponents beat themselves.

... if you choose to win at tennis – as opposed to having a good time – the strategy for winning is to avoid mistakes. The way to avoid mistakes is to be conservative and keep the ball in play, letting the other fellow have plenty of room in which to blunder his way to defeat, because he, being an amateur will play a losing game and not know it.

While the amateur can't *consistently* hit winners, they want to. When amateurs play a Winner's game, they force shots that have a low probability of winning and a high probability of error. While they might hit the occasional winner, the ratio between winning shots and losing shots is skewed heavily toward losers.

Sometimes amateurs convince themselves they are professionals, but professionals never convince themselves they are amateurs. Professionals know they are not playing the same game as amateurs.

If you are within your circle of competence, seek brilliance. If you are not, avoid stupidity.

Investors Bet on Someone Else's Game

This reminds me of something.

Warren Buffett used to convene a group of people called the *Buffett Group*. At one such meeting, Benjamin Graham, Buffett's mentor, gave them all a quiz. I spent hours searching for this reference, which comes from *Benjamin Graham on Value Investing: Lessons from the Dean of Wall Street*.

"He gave us a quiz," Buffett said, "A true-false quiz. And there were all these guys who were very smart. He told us ahead of time that half were true and half were false. There were 20 questions. Most of us got less than 10 right. If we'd marked every one true or every one false, we would have gotten 10 right."

Graham made up the deceptively simple historical puzzler himself, Buffett explained. "It was to illustrate a point, that the smart fellow kind of rigs the game. It was 1968, when all this phoney accounting was going on. You'd think you could profit from it by riding along on the coattails, but (the quiz) was to illustrate that if you tried to play the other guy's game, it was not easy to do."

"Roy Tolles got the highest score, I remember that," Buffett chuckled. "We had a great time. We decided to keep doing it."

Avoiding Stupidity is Easier Than Seeking Brilliance

The point is that most of us are amateurs but we refuse to believe it.

This is a problem because we're often playing the game of the professionals. What we should do in this case, when we're the amateur, is to invert the problem. Rather than trying to win, we should avoid losing.

This was a point Charlie Munger, the billionaire business partner of Warren Buffett made a long time ago.

In a letter to Wesco Shareholders, where he was at the time Chairman (Found in *Damn Right!: Behind the Scenes with Berkshire Hathaway Billionaire Charlie Munger*), Munger writes:

Wesco continues to try more to profit from always remembering the obvious than from grasping the esoteric. ... It is remarkable how much long-term advantage people like us have gotten by trying to be consistently not stupid, instead of trying to be very intelligent. There must be some wisdom in the folk saying, 'It's the strong swimmers who drown.'

And there is so much wisdom embedded in that quote that I've printed it out and attached it to my wall.

63. Keeping Things Simple and Tuning out Folly

Keeping things simple makes a huge difference and yet we are drawn to the sexiness of complexity. Einstein was a master of sifting the essential from the non-essential.

And consider this from Charlie Munger: The Complete Investor:

Peter Bevelin's book Seeking Wisdom: From Darwin to Munger has a section on the importance of simplicity.

Bevelin advised: "Turn complicated problems into simple ones. Break down a problem into its components, but look at the problem holistically." Keeping things as simple as possible, but no more so, is a constant theme in Munger's public statements. In a joint letter to shareholders, Munger and Buffett once wrote: "Simplicity has a way of improving performance through enabling us to better understand what we are doing."

[...]

By focusing on finding decisions and bets that are easy, avoiding what is hard, and stripping away anything that is extraneous, Munger believes that an investor can make better decisions. By "tuning out folly" and swatting away unimportant things "so your mind isn't cluttered with them ... you're better able to pick up a few sensible things to do," said Munger. Focus enables both simplicity and clarity of thought, which in Munger's view leads to a more positive investing result.

"If something is too hard, we move on to something else. What could be simpler than that?"

— Charlie Munger

There is a compelling advantage in life to be found in exploiting unrecognized simplicities, something Peter Thiel tries to tease out in interviews. Essential to recognizing simplicity is scheduling time to think.

"We have three baskets: in, out, and too tough... We have to have a special insight, or we'll put it in the too tough basket."

— Charlie Munger

Simplicity is Filtering

William James said: "The art of being wise is the art of knowing what to overlook." And there are no truer words that have been spoken.

In Arthur Conan Doyle's The Reigate Puzzle, Sherlock Holmes says: "It is of the highest importance in the art of detection to be able to recognize, out of a number of facts, which are incidental and which vital."

And part of filtering is understanding what you know and what you don't know, that is, understanding your circle of competence.

"We have a passion for keeping things simple."

— Charlie Munger

In an interview with Jason Zweig, Munger said:

Confucius said that real knowledge is knowing the extent of one's ignorance. Aristotle and Socrates said the same thing. Is it a skill that can be taught or learned? It probably can, if you have enough of a stake riding on the outcome. Some people are extraordinarily good at knowing the limits of their knowledge, because they have to be. Think of somebody who's been a professional tightrope walker for 20 years—and has survived. He couldn't survive as a tightrope walker for 20 years unless he knows exactly what he knows and what he doesn't know. He's worked so hard at it, because he knows if he gets it wrong he won't survive. The survivors know.

Another time he offered:

Part of that [having uncommon sense], I think, is being able to tune out folly, as distinguished from recognizing wisdom. You've got whole categories of things you just bat away so your brain isn't cluttered with them. That way, you're better able to pick up a few sensible things to do.

Warren Buffett, the CEO of Berkshire Hathaway agrees:

Yeah, we don't consider many stupid things. I mean, we get rid of 'em fast.. Just getting rid of the nonsense — just figuring out that if people call you and say, "I've got this great, wonderful idea", you don't spend 10 minutes once you know in the first sentence that it isn't a great, wonderful idea... Don't be polite and go through the whole process.

And Peter Bevelin, writing in Seeking Wisdom, offers:

Often we try to get too much information, including misinformation, or information of no use to explain or predict. We also focus on details and what's irrelevant or unknowable and overlook the obvious truths. Dealing with what's important forces us to prioritize. There are often just a few actions that produce most of what we are trying to achieve. There are only a few decisions of real importance.

More information doesn't equal more knowledge or better decisions. And remember that today we not only have access to more information, but also misinformation.

And the harder we work at something the more confident we become.

It's worth pausing to reflect on three things at this point: 1) understanding and seeking simplicity; 2) dealing with the easy problems first; and 3) honing your skills by learning what to overlook and getting rid of bad ideas quickly (how many organizations do that!?)... this goes hand in hand with understanding your circle of competence.

64. Your Environment Shapes Your Decisions

When it comes to making decisions, your environment matters. Just as it's hard to eat healthily if your kitchen is full of junk food, it's hard to make good decisions when you're too busy to think. Just as the kitchen influences what you eat, your office influences how you make decisions.

The Modern Office is Terrible for Thinking

No one understands how your environment shapes your ability to make decisions more than Warren Buffett and Charlie Munger. While they're gifted with intellect, they make sure they get the most out of it by structuring their environment to help them make good decisions.

Most of us make decisions in an environment where it is very hard for us to behave rationally.

You can't design a worse environment for good decisions than the modern office. When you first arrive at work, you immediately start to answer the critical emails from your swelling inbox. The inner voice in your head tells you don't worry; you'll get to the rest later. Suddenly, the phone rings, it's your boss wanting to know if you have time to chat on the 15-page proposal she was supposed to read for the meeting in 30 minutes. But you haven't read the proposal either. So you glance at the executive summary and, like anyone that has learned to survive in an office, you confidently act like you know what's going on. You haven't done the work to have an opinion. But that's the game. Everyone else did the same thing. When you finally lift your head up, your email box is swelling again, you have missed calls, and it's almost time to pick up the kids from school. Where did the day go? This isn't an abnormal day. This is every day. From the moment you arrive until the moment you leave, you make an inch of progress on twenty things rather than ten feet of progress on one thing.

The unwritten rule is that you have to do these things to justify your job. If you're not pushing paper, firing up hundreds of emails, calling and attending meetings, and chasing something down ... just what the heck are you doing?

The cultural environment is typically about politics and signalling, not about putting people in a position to succeed. The physical environment is about busyness and distraction, not focus and thinking. Neither of these environments line up with the good decision making. Contrast this to Warren Buffett. He has no computer in his office. He's not distracted every few minutes by that annoying little ding that signals a new email has arrived. His day isn't full of meetings. He doesn't have an annoying boss that comes around and asks him for something tangible that's he's working on. He just reads and thinks. No wonder he's so good at it.

If you want to think for yourself, you can't have someone always whispering in your ear. If you want space to think, you need quiet and calm not a bunch of smart people throwing out new ideas. That's why Buffett moved from New York to Omaha. "In some places, it's easy to lose perspective. But I think it's very easy to keep perspective in a place like Omaha," Buffett says. He continues:

It's very easy to think clearly here. You're undisturbed by irrelevant factors and the noise generally of business investments. If you can't think clearly in Omaha, you're not going to think clearly anywhere.

Putting Buffett in a modern office is like giving Superman kryptonite. His superpowers would disappear. He wouldn't be able to think and concentrate. Luckily, he intentionally set up his environment in a way that makes it easier to behave rationally.

The (Super) Power of Environment

We influence our environments, but we forget they influence us too.

We like to believe that we are in charge that our brains are only influenced by our conscious thoughts. That sounds amazing, but it's wrong. Our conscious brain is much

smaller than our subconscious brain. And yet when it comes to getting better at thinking and making decisions, we place all the emphasis on the conscious brain, learning mental models and methods of thinking that improve outcomes. In so doing, we improve the raw horsepower of our brain. Yet, there is no point having a 400 horsepower engine if you can only get 25 horsepower out of it.

Designing an Effective Environment

There is no environment that works for everyone. We all respond differently to different stimuli. A corner office on the 100th floor in New York might provide inspiration to some and distraction to others. What works for me might not work for you.

Here are three things we've found work for a lot of different people in a lot of different situations.

First, structure your day to maximize your energy. Most people do the tasks requiring the least amount of thought (answering emails, checking voicemails, catching up with people) in the morning when they are most productive. Meetings and decisions get pushed to the afternoon when our brains are not working as well. Switch your day around. Do the most important thing first.

Second, use chunks of time and be conscious when interrupting other people. Block chunks of time in your calendar for your own projects. I don't mean like 20 minutes, I mean like hours. I have every morning blocked off from 9-12. It's not easy to get into a state of flow, but once you're there, you're focused on one thing. It could be thinking about a problem in a three dimensional way or refining a report that you're writing for work. If you interrupt this time, it's expensive to get back to where you were, often taking 25 minutes or more to recover. Keep that in mind when you interrupt others.

Third, make effective behaviors easy. If there is chocolate in our office, you can be sure I'll eat it. That's why I lock the good stuff in a safe. Literally. This makes it harder to get to, and I eat less of it. OK, you probably want a better example than chocolate. Here's one I used to use at work. On the first page of my notebook at the intelligence agency, I listed some general thinking tools that I could fall back on for tough decisions. This prompted me to think through problems in a structured way and saved me from more than one mess.

(Update: These are now a book).

Your Environment Matters More Than You Think

We intuitively know that the physical and cultural environment matters.

You don't control everything in your environment, but you control enough to make a huge difference. Think about what you control and how you can change it to get more horsepower out of your brain.

65. What Matters More in Decisions: Analysis or Process?

We all make decisions. Some of them are large and many of them are small. Few of us understand that the process we use to make those decisions is more important than the analysis we put into the decision.

Think of the last major decision you made.

Maybe it was an acquisition, a large purchase, or perhaps it was whether to launch a new product.

Odds are three things went into that decision: (1) It probably relied on the insights of a few key executives; (2) it involved some sort of fact gathering and analysis; and (3) it was likely enveloped in some sort of decision process—whether formal or informal—that translated the analysis into a decision.

Now how would you rate the *quality* of your organization's strategic decisions?

If you're like most executives, the answer wouldn't be positive:

In a recent McKinsey Quarterly survey of 2,207 executives, only 28 percent said that the quality of strategic decisions in their companies was generally good, 60 percent thought that bad decisions were about as frequent as good ones, and the remaining 12 percent thought good decisions were altogether infrequent.

How could it be otherwise? Product launches are frequently behind schedule and over budget. Strategic plans often ignore even the anticipated response of competitors.

Mergers routinely fail to live up to the promises made in press releases.

The persistence of problems across time and organizations, both large and small, indicates that we can make better decisions.

"I have no use whatsoever for projections or forecasts. They create an illusion of apparent precision. The more meticulous they are, the more concerned you should be. We never look at projections."

— Warren Buffett

The best place to start if we're trying to improve the quality of our decisions is to look at how organizations make decisions. One interesting thing about bureaucracies is that they develop processes to limit the damage the worst people can do at every level. That is they come up with mechanisms to reduce the impact the worst people can have. Yes, this also limits the positive impact that people can have as well. When it comes to decisions, organizations default to gathering data and analyzing decisions.

The widespread belief is that analysis reduces biases. But does it?

Is putting your faith in analysis any better than using your gut? What does the evidence say? Is there a better way?

Dan Lovallo and Olivier Sibony set to find out.

Lovallo is a professor at the University of Sydney and Olivier is a director at McKinsey & Company. Together they studied 1,048 "major" business decisions over five years. The results are surprising.

Most business decisions were not made on "gut calls" but rather rigorous analysis. And yet they were poor decisions. In short, most people did the all the legwork we think we're supposed to do: they delivered large quantities of detailed analysis.

Yet this wasn't enough. "Our research indicates that, contrary to what one might assume, good analysis in the hands of managers who have good judgment won't naturally yield good decisions."

[Projections] are put together by people who have an interest in a particular outcome, have a subconscious bias, and its apparent precision makes it fallacious. They remind me of Mark Twain's saying, 'A mine is a hole in the ground owned by a liar.' Projections in

America are often a lie, although not an intentional one, but the worst kind because the forecaster often believes them himself."

— Charlie Munger

Lovallo and Sibony didn't only look at the analysis, they also asked executives about the process used to make decisions.

Did they, for example, "explicitly explore and discuss major uncertainties or discuss viewpoints that contradicted the senior leader's?"

So what matters more, process or analysis? After comparing the results they determined that "process mattered more than analysis—by a factor of six."

This finding does not mean that analysis is unimportant, as a closer look at the data reveals: almost no decisions in our sample made through a very strong process were backed by very poor analysis. Why? Because one of the things an unbiased decision-making process will do is ferret out poor analysis. The reverse is not true; superb analysis is useless unless the decision process gives it a fair hearing.

To illustrate the weakness of how most organizations make decisions, Sibony used an interesting analogy: the legal system.

Imagine walking into a courtroom where the trial consists of a prosecutor presenting PowerPoint slides. In 20 pretty compelling charts, he demonstrates why the defendant is guilty. The judge then challenges some of the facts of the presentation, but the prosecutor has a good answer to every objection. So the judge decides, and the accused man is sentenced.

That wouldn't be due process, right? So if you would find this process shocking in a courtroom, why is it acceptable when you make an investment decision? Now of course, this is an oversimplification, but this process is essentially the one most companies follow to make a decision. They have a team arguing only one side of the case. The team has a choice of what points it wants to make and what way it wants to make them. And it falls to the final decision maker to be both the challenger and the ultimate judge. Building a good decision-making process is largely ensuring that these flaws don't happen.

Simply understanding our cognitive biases doesn't make you immune to them. It's not enough. A disciplined decision process is the best place to improve the quality of decisions and guard against common decision-making biases.

66. Why Bad Things Happen to Good Decisions

Good decisions don't always have a good outcome, just as bad decisions don't always have bad outcomes. Sometimes bad outcomes happen to good decisions. And sometimes good things happen to bad decisions. Learning to distinguish between when you're brilliant and lucky is the key to rapid improvement.

When other people make decisions with bad outcomes, we tend to focus on the people behind the decision. We can't seem to shake the belief that good people make good decisions and bad people make bad decisions. It's easy to think that we would have made a better decision.

When our decisions have bad outcomes, we know the outcomes is not all there is to see. Our thoughts and intentions come into play. We can't see the thoughts and intentions of others—we only see their actions through a biased lens. We can, however, see our thoughts and intentions. Our bad outcomes happen because we were unlucky.

The Decision Outcome Matrix

Consider this simple two-by-two decision outcome matrix.

	Good Outcome	Bad Outcome
Good Process	What we are aiming for.	We are not omniscient. We need courage to weather this. Your system will not work every time, and it is easy to abandon the system the first time it fails.
Bad Process	Gambling and winning. Feeds the halo effect.	Gambling and losing. My bad luck, your poor skill.

We want to deserve success. Everyone wants to be in the upper left box — a good process that results in a good outcome. The problem is the world doesn't always comply with our wishes. Following a good process can lead to a bad outcome because of uncertainty.

A good process with a bad outcome requires that we remember nothing is for sure. Bad outcomes from a bad process require a choice. If we are delusional and let our ego dominate, we mistakenly see this as bad luck. While we are aware that we had a negative outcome, we are unaware that it resulted from a bad process. In this case, we learn nothing. We are doomed to repeat our mistakes. More self-reflective people see bad

outcomes resulting from bad process as an opportunity to learn as much as we can to avoid repeat failures.

Perhaps the worst quadrant to be in is the lower left — a bad process leads to a good outcome. Ignoring the fact that this isn't repeatable, we convince ourselves that we deserved success.

If you can't recognize when you've had 'dumb luck,' you'll never be in a position to correct the way you're making decisions. Eventually, your luck runs out.

Of course, it's easier to place others into the matrix than ourselves. When it comes to others, we see more of reality because we're a disconnected observer. When it comes to ourselves, however, we default to ego protection.

One of the ways to calibrate your decisions is to use a decision journal. A good decision is known *before* the outcome. It involves a mental representation of the facts known at the time as well as applied judgment. Good decisions are valuable, but they are more valuable if they are part of a good decision process because a good process allows for feedback about where you can improve. This feedback, in turn, allows you to constantly get better at making decisions.

Article Summary:

- Good decisions don't always have a good outcome. Bad decisions don't always have bad outcomes.
- Bad outcomes can happen to good decisions.
- When other people have a bad outcome, we tend to think they made a bad decision. When we have a bad outcome, we tend to focus on intentions.
- There is a simple 2*2 matrix to help you see what happened. On one axis is Good/Bad Process, on the other is good/bad outcome.
- A bad process with a good outcome is gambling and winning. This is the most dangerous quadrant.
- A bad process with a bad outcome is gambling and losing.
- A good process with a bad outcome needs to be put into perspective.
- You can calibrate your decisions using a decision journal.

67. William Morris: Adventures in Decision-Making

This isn't my advice, it comes from the 1973 book How to Get Rich Slowly, But Almost Surely: Adventures in Decision-Making by William Morris.

"It's foolish," Morris writes, "to suppose that anyone could give you a set of rules for making ... decisions which you would actually follow. Something of greater subtlety, but also of greater practicality is involved."

It's useful to make judgments about the quality and effectiveness of your decision making. Only when you look at how you make decisions, will actual behavioral changes result. *You've got to begin by appreciating your own self-image by seeing your own style, and by becoming conscious of what you ordinarily do without the slightest self-consciousness. Then compensation and change will begin to occur, almost entirely without effort on your part.*

So, let's take a precise look at our behavior in the way we make decisions. How do we make decisions?

Here are some questions to ask (Keep in mind that one style of deciding isn't necessarily better than another):

To what extent is your style of decision making intuitive, implicit and private? To what extent is it analytical, explicit, and open?

To what degree are you tolerant of ambiguity in a decision situation? Can you decide in the face of ambiguous notions about objectives or ambiguous statements of the alternative courses of action? Some studies suggest that experienced decision makers are highly tolerate of ambiguity and capable of resolving it in their own special ways.

Similarly, to what degree are you tolerant of uncertainty as to the consequences of various actions? Some of us require considerable information and assurances before we will act, others are far more willing to act on the basis of limited information and substantial uncertainty. We should not imagine that one such style is always "better" than the other.

How reasonable is your hindsight? How effectively do you learn from your past decisions? Are you given to regretting decisions which turn out badly or do you suppress these feelings and look to the future? Do you distinguish clearly between a good decision which depends on reason and logic, and a good result or outcome which always depends to some degree on chance, luck and circumstances beyond your control.

How much cognitive effort to you invest in a decision? Some decision makers are careful and deliberate thinkers, others tend to proceed "off the top of their heads" or "by the seat of their pants."

To what degree do you seek external aids or outside help in deciding?

To what extent is there a need for coherence between your beliefs, your actions, and your objectives?

We may seek coherence by becoming more optimistic about a course of action after we have chosen it, than before. Sometimes we adopt the belief that what we have become committed to is the best possible course of action, while we had no such conviction prior to our commitment. We achieve coherence or reduce "cognitive dissonance" by revising our preconceptions.

How sensitive are your unaided decision making ability to conditions of stress? There is considerable evidence that most of us become distinctly poorer decision makers when we are under stress or pressure.

To what extent are your perceptions and thoughts influenced, not so much by the external world, as by our own needs and desires. One of the great discoveries of modern psychology is that what we see and what we think are influenced subconsciously by our needs and tensions.

To what degree are you clear about your own decision making processes? How much self-knowledge or self-consciousness do you have in this connection? It is well established

that we seldom understand very well the reasons we do what we do, or the goals we are striving to attain.

To what degree are your perceptions of the external world distorted because of distortions shared by your associates? Science is full of instances of socially shared distortions, often going about under the heading of "common sense." Indeed, one of the best definitions of common sense pictures it as that kind of sense which tells us when we look out of the window that the world is flat.

To what degree do you abstract or simplify the external world in making a decision?

To what degree do you rely on rules of thumb or platitudes for disposing of decision problems?

To what degree do you look ahead in a decision? Is the planning horizon in the relatively near, or relatively distant future? One of the skills of a good chess player is his ability to look ahead to the future consequences of his moves. The ability of computers to play chess is rather directly related to their "look-ahead" ability.

When things are looking very bad, how good are you at remaining clam and free from a slight panicky feeling?

How much experience do you have in living with the consequences of your choices? Have you made some "big" decisions?

How strong is your desire to get immediate, remarkable results when you make a decision?

What can you say about your ability to see the facts, the data, both sides of a question, when you are confronted with an emotionally charged decision situation?

How do you rate yourself in terms of self-confidence and respect for your own abilities?

How capable are you of filtering through the giving structure to large volumes of information?

Do you have a tendency to write down important considerations when you have to make a decision of some consequence?

68. The Remarkable Way We Gain Insights

In 1936 Graham Wallas, co-founder of the London School of Economics, published The Art of Thought, outlining the four stages of the creative process. This pre-dates, by at least a decade, James Webb's A Technique for Producing Ideas.

Wallas's model "is still the most common explanation of how insight works. If you do any exploration into the field of insight, you can't go far without bumping into Wallas, who is the epitome of a British freethinking intellectual," writes Gary Klein in Seeing What Others Don't: The Remarkable Ways We Gain Insights.

The Creativity Question, published in 1976, preserves Wallas's "Stages of Control" and presents his model of insight: (1) preparation; (2) incubation; (3) illumination; and (4) verification.

In Seeing What Others Don't: The Remarkable Ways We Gain Insights, Klein summarizes: *During the preparation stage we investigate a problem, applying ourselves to an analysis that is hard, conscious, systematic, but fruitless.*

Then we shift to the incubation stage, in which we stop consciously thinking about the problem and let our unconscious mind take over. Wallas quoted the German physicist Hermann von Helmholtz, who in 1891 at the end of his career offered some reflections on how this incubation stage feels. After working hard on a project, Helmholtz explained that "happy ideas come unexpectedly without effort, like an inspiration. So far as I am concerned, they have never come to me when my mind was fatigued, or when I was at my working table. They came particularly readily during the slow ascent of wooded hills on a sunny day."

Wallas advised his readers to take this incubation stage seriously. We should seek out mental relaxation and stop thinking about the problem. We should avoid anything that might interfere with the free working of the unconscious mind, such as reading serious materials.

...

Next comes the illumination stage, when insight bursts forth with conciseness, suddenness, and immediate certainty. Wallas believed that the insight, the "happy idea," was the culmination of a train of unconscious associations. These associations had to mature outside of conscious scrutiny until they were ready to surface. Wallas claimed that people could sometimes sense that an insight was brewing in their minds. The insight starts to make its appearance in fringe consciousness, giving people an intimation that the flash of illumination is nearby. At this point the insight might drift away and not evolve into consciousness. Or it might get interrupted by an intrusion that causes it to miscarry. That's why if people feel this intimation arising while reading, they often stop and gaze out into space, waiting for the insight to appear. Wallas warned of the danger of trying to put the insight into words too quickly, before it was fully formed.

Finally, during the verification stage we test whether the idea is valid. If the insight is about a topic such as mathematics, we may need to consciously work out the details during this final stage.

Wallas noted that none of these stages exist in isolation.

In the daily stream of thought these four different stages constantly overlap each other as we explore different problems. An economist reading a Blue Book, a physiologist watching an experiment, or a business man going through his morning's letters, may at the same time be "incubating" on a problem which he proposed to himself a few days ago, be accumulating knowledge in "preparation" for a second problem, and be "verifying" his conclusions on a third problem. Even in exploring the same problem, the mind may be unconsciously incubating on one aspect of it, while it is consciously employed in preparing for or verifying another aspect. And it must always be remembered that much very important thinking, done for instance by a poet exploring his own memories, or by a man

trying to see clearly his emotional relation to his country or his party, resembles musical composition in that the stages leading to success are not very easily fitted into a “problem and solution” scheme. Yet, even when success in thought means the creation of something felt to be beautiful and true rather than the solution of a prescribed problem, the four stages of Preparation, Incubation, Illumination, and the Verification of the final result can generally be distinguished from each other. (The Creativity Question)

If you talk to anyone about insight today, most people are familiar with the model Wallas proposed.

“It’s a very satisfying explanation that has a ring of plausibility,” writes Klein, “until we examine it more closely.”

Klein points to many counterexamples where people had insights that came unexpectedly, without a preparation stage. A lot of people aren’t wrestling with a problem when they come up with an accidental insight.

According to Wallas, when we’re stuck and need to find an insight that will get us past an impasse, we should start with deliberate preparation. ... One flaw in Wallas’s method is that his sample of cases was skewed. He only studied success stories. He didn’t consider all the cases in which people prepared very hard but got nowhere. (Seeing What Others Don’t: The Remarkable Ways We Gain Insights)

Specific preparation doesn’t always lead to insights. And the people who gain insights may or may not follow the Wallas model, so perhaps it is incomplete.

We need another theory.

Discontinuous Discoveries

Sometimes shifts in thinking are not about making minor adjustments or adding details.

Sometimes we fundamentally shift core beliefs. This allows us to see the problem in a new way and may lead to insight. We shift from a poor story to a better one. These are discontinuous discoveries.

Insights shift us toward a new story, a new set of beliefs that are more accurate, more comprehensive, and more useful. Our insights transform us in several ways. They change how we understand, act, see, feel, and desire. They change how we understand. They transform our thinking; our new story gives us a different viewpoint. They change how we act. ... Insights transform how we see; we look for different things in keeping with our new story. (Seeing What Others Don’t)

In Wolf Hall, Hilary Mantel makes an important observation, “Insight cannot be taken back. You cannot return to the moment you were in before.” After insight, everything is different.

Insights are unique in some other ways:

When they do appear, they are coherent and unambiguous. They don’t come as part of a set of possible answers. When we have the insight, we think, “Oh yes, that’s it.” We feel a sense of closure. This sense of closure produces a feeling of confidence in the insight.

(Seeing What Others Don’t)

The Difference Between Insight and Intuition

Intuition is the use of patterns they’ve already learned, whereas insight is the discovery of new patterns. (Seeing What Others Don’t)

The Role of Stories

Stories are a way we frame and organize the details of a situation. There are other types of frames besides stories, such as maps and even organizational wiring diagrams that show where people stand in a hierarchy. ... These kinds of stories organize all kinds of details about a situation and depend on a few core beliefs we can call “anchors,” because they are fairly stable and anchor the way we interpret the other details. (Seeing What Others Don’t)

And anchors can change. They change when we get new information. They change when we shift our beliefs.

What causes us to change our story? Klein proposes five strategies connections, coincidences, curiosities, contradictions, and creative desperation.

In all of these cases we change our story.

When faced with creative desperation, we try to find a weak belief that is trapping us. We want to jettison this belief so that we can escape from fixation and from impasse. In contrast, when using a contradiction strategy, we center on the weak belief. We take it seriously instead of explaining it away or trying to jettison it. We use it to rebuild our story.

(Seeing What Others Don't)

When we're desperate, we're more likely to attack a weak anchor and give something a try.

In times of desperation, we actively search for an assumption we can reverse. We don't seek to imagine the implications if the assumption was valid. Rather, we try to improve the situation by eliminating the assumption. (Seeing What Others Don't)

But changing our story is not the only way to gain insight. We can also add new anchors.

The Triple Path

In the end, Klein came up with the tripe path model of insight, which tries to capture the similarities between the strategies.

Source: Seeing What Others Don't: The Remarkable Ways We Gain Insights

The connection path is different from the desperation path or the contradiction path. We're not attacking or building on weak anchors. When we make connections or notice coincidences or curiosities, we add a new anchor to our beliefs and then work out the implications. Usually the new anchor comes from a new piece of information we receive.

...

I've combined the connections, coincidences, and curiosities in the Triple Path Model. They have the same dynamic: to build on a new potential anchor. They have the same trigger: our thinking is stimulated when we notice the new anchor. Coincidences and curiosities aren't insights in themselves; they start us on the path to identifying a new anchor that we connect to the other beliefs we hold. Connections, coincidences, and curiosities have the same activity: to combine the new anchor with others. This path to insight doesn't force us to abandon other anchors. It lets us build a new story that shifts our understanding. This path has a different motivation, a different trigger, and a different activity from the contradiction and the creative desperation paths. Nevertheless, like the other two paths, the outcome is the same: an unexpected shift in the story. Each of the three paths, the contradiction path, the connection path, and the creative desperation path, gets sparked in a different way. And each operates in a different fashion: to embrace an anomaly that seems like a weak anchor in a frame, to overturn that weak anchor, or to add a new anchor. Future work on insight is likely to uncover other paths to insight besides the three shown in the diagram. (Seeing What Others Don't)

Other people weren't wrong, they were just following one path. The Triple Path Model shows why earlier accounts aren't wrong as much as they are incomplete. They restrict themselves to a single path. Researchers and theorists such as Wallas who describe insight as escaping from fixation and impasses are referring to the creative desperation path. Researchers who emphasize seeing associations and combinations of ideas are referring to the connection path. Researchers who describe insight as reformulating the problem or restructuring how people think have gravitated to the contradiction path. None of them are wrong. The Triple Path Model of insight illustrates why people seem to be talking past each other. It's because they're on different paths. (Seeing What Others Don't)

69. Eric Drexler on taking action in the face of limited knowledge

Science pursues answers to questions, but not always the questions that engineering must ask.

The founding father of nanotechnology, Eric Drexler, who aptly described the difference between science and engineering, comments on the central differences between how science and engineering approach solutions in a world of limited knowledge.

Drexler's explanation, found in his insightful book Radical Abundance: How a Revolution in Nanotechnology Will Change Civilization, discusses how there is a certain amount of ignorance that pervades everything. How, then, should we respond? Engineers apply a margin of safety.

Drexler writes:

When faced with imprecise knowledge, a scientist will be inclined to improve it, yet an engineer will routinely accept it. Might predictions be wrong by as much as 10 percent, and for poorly understood reasons? The reasons may pose a difficult scientific puzzle, yet an engineer might see no problem at all. Add a 50 percent margin of safety, and move on. Safety margins are standard parts of design, and imprecise knowledge is but one of many reasons.

Engineers and scientists ask different questions:

... Accuracy can only be judged with respect to a purpose and engineers often can choose to ask questions for which models give good-enough answers.

The moral of the story: Beware of mistaking the precise knowledge that scientists naturally seek for the reliable knowledge that engineers actually need.

Nature presents puzzles that thwart human understanding.

Some of this is necessary fallibility—some things we simply cannot understand or predict. Just because we want to understand something doesn't mean it's within our capacity to do so.

Other problems represent limited understanding and predictability — there are things we simply cannot do yet, for a variety of reasons.

... Predicting the weather, predicting the folding of membrane proteins, predicting how particular molecules will fit together to form a crystal— all of these problems are long-standing areas of research that have achieved substantial but only partial success. In each of these cases, the unpredictable objects of study result from a spontaneous process— evolution, crystallization, atmospheric dynamics— and none has the essential features of engineering design.

What leads to system-level predictability?

— *Well-understood parts with predictable local interactions, whether predictability stems from calculation or testing*

— *Design margins and controlled system dynamics to limit the effects of imprecision and variable conditions*

— *Modular organization, to facilitate calculation and testing and to insulate subsystems from one another and the external*

... When judging engineering concepts, beware of assuming that familiar concerns will cause problems in systems designed to avoid them.

Seeking Unique Answers vs. Seeking Multiple Options

Expanding the range of possibilities plays opposite roles in inquiry and design.

If elephantologists have three viable hypotheses about an animal's ancestry, at least two hypotheses must be wrong. Discovering yet another possible line of descent creates more uncertainty, not less— now three must be wrong. In science, alternatives represent ignorance.

If automobile engineers have three viable designs for a car's suspension, all three designs will presumably work. Finding yet another design reduces overall risk and increases the

likelihood that at least one of the designs will be excellent. In engineering, alternatives represent options. Not knowing which scientific hypothesis is true isn't at all like having a choice of engineering solutions. Once again, what may seem like similar questions in science and engineering are more nearly opposite.

Knowledge of options is sometimes mistaken for ignorance of facts.

Remarkably, in engineering, even scientific uncertainty can contribute to knowledge, because uncertainty about scientific facts can suggest engineering options.

Simple, Specific Theories vs. Complex, Flexible Designs

Engineers value what scientists don't: flexibility.

Science likewise has no use for a theory that can be adjusted to fit arbitrary data, because a theory that fits anything forbids nothing, which is to say that it makes no predictions at all. In developing designs, by contrast, engineers prize flexibility — a design that can be adjusted to fit more requirements can solve more problems. The components of the Saturn V vehicle fit together because the design of each component could be adjusted to fit its role.

In science, a theory should be easy to state and within reach of an individual's understanding. In engineering, however, a fully detailed design might fill a truck if printed out on paper.

This is why engineers must sometimes design, analyze, and judge concepts while working with descriptions that take masses of detail for granted. A million parameters may be left unspecified, but these parameters represent adjustable engineering options, not scientific uncertainty; they represent, not a uselessly bloated and flexible theory, but a stage in a process that routinely culminates in a fully specified product.

...

Beware of judging designs as if they were theories in science. An esthetic that demands uniqueness and simplicity is simply misplaced.

Curiosity-Driven Investigation vs. Goal-Oriented Development

The organizational structure differs between scientific and engineering pursuits. The coordination of work isn't interchangeable.

In science, independent exploration by groups with diverse ideas leads to discovery, while in systems engineering, independent work would lead to nothing of use, because building a tightly integrated system requires tight coordination. Small, independent teams can design simple devices, but never a higher-order system like a passenger jet.

...

In inquiry, investigator-led, curiosity-driven research is essential and productive. If the goal is to engineer complex products, however, even the most brilliant independent work will reliably produce no results.

...

The moral of the story: Beware of approaching engineering as if it were science, because this mistake has opportunity costs that reduce the value of science itself.

In closing, Drexler comments on applying the engineering perspective.

Drawing on established knowledge to expand human capabilities, by contrast, requires an intellectual discipline that, in its fullest, high-level form, differs from science in almost every respect.

70. More Information Doesn't Mean Better Decisions

We tend to think that if we only had more information, we'd make better decisions. The world, however, doesn't always work that way. Paradoxically, More information often means that we make worse decisions.

When you want to make a good decision, your first action is most likely to collect more information. If you know more about the situation, you can make better judgments. Right? Not always. Paradoxically, more information can lead us to make worse decisions. One of the reasons we make worse decisions with more information is that we pursue information that appears relevant but isn't. The harder the information is to find—that is, the more work we have to do to find it and the more exclusive is it—the more psychology tells us that we'll put too much value on that information. In part, this happens because of our bias toward commitment and consistency; we've spent time and effort seeking out that information, so mentally, we feel obliged to use it. This nudges us toward decisions we otherwise wouldn't have made. We also over-value information that is easily obtainable, thinking that it possesses unique insights when, in fact, it's nothing more than you'd find on the first page of Google. A little knowledge truly is a dangerous thing.

“
**We love irrelevant
information because
we lack a fundamental
understanding of what
variables matter and how
they interact.**

”

— Shane Parrish —

fs

And yet, another reason we love irrelevant information is that we really lack fundamental understanding.

If we don't understand something, we won't have a firm grasp of the fundamental variables that govern the situation and how they interact, so we'll look for new variables. When you're not sure how to weigh one attribute compared with another, you end up searching for a reason.

Often this mountain of new information — even if easily obtainable — is largely irrelevant to the situation. The problem is we don't know it is irrelevant.

“The result is that peculiar feeling of inward unrest known as indecision. Fortunately, it is too familiar to need description, for to describe it would be impossible. As long as it lasts, with the various objects before the attention, we are said to deliberate; and when finally the original suggestion either prevails and makes the movement take place, or gets definitively quenched by its antagonists, we are said to decide, or to utter our voluntary fiat in favor of one or the other course. The reinforcing and inhibiting ideas meanwhile are termed the reasons or motives by which the decision is brought about.”

— William James

Decisions

Decisions are hard to make. In part, this is because of conflict and uncertainty. We are uncertain of the consequences of our actions and have difficulty making tradeoffs between attributes. Just as knowledge can make decision making easier, a lack of knowledge compounds the problem.

When faced with two choices of equal alternatives, Slovic (1975, 1990) suggests we make choices based on what's easy to explain and justify. Sounds logical, right, why flip a coin when I can come up with a reason.

Sometimes we weigh the pros and cons. Subconsciously, when deciding for something, we focus on the pros, and when we decide against something, we focus on the reasons for rejection. This has the added advantage of giving us a good story to tell but causes problems when there are no striking positive or negative aspects to help make the decision.

When we can't find a compelling reason to do something or avoid something, we are left in a state of conflict. So we search for more information.

"Seeking new alternatives usually requires additional time and effort and may involve the risk of losing the previously available options."

— Amos Tversky and Shafir

The implications of my cobbled together theory seem worth considering.

If our current choices don't give us a convincing reason to opt for a choice, we'll likely seek out additional information (rather than questioning our understanding). When we do seek out additional information, we're really just looking for a compelling rationale for choosing one alternative over another.

The more we look for a new rationale to make decisions, the further we are from understanding. The harder we look, the more we'll find. The more we find, the more we'll miss-weigh what we find. The more we miss-weigh, the more likely we are to make a poor decision.

So the next time you find yourself seeking out hard-to-find esoteric information to give yourself an edge in that important decision, think hard about whether you understand the fundamentals of the situation. The more esoteric information you seek the further you move from the likely variables that will govern the outcomes of the situation.

71. Decisions Under Uncertainty

If you're a knowledge worker you make decisions every day. In fact, whether you realize it or not, decisions are your job.

Decisions are how you make a living. Of course, not every decision is easy. Decisions tend to fall into different categories. The way we approach the actual decision should vary based on category.

Here are a few basic categories that decisions fall into.

There are decisions where:

1. Outcomes are known. In this case, the range of outcomes is known and the individual outcome is also known. This is the easiest way to make decisions. If I hold out my hand and drop a ball, it will fall to the ground. I know this with near certainty.
2. Outcomes are unknown, but probabilities are known. In this case, the range of outcomes are known but the individual outcome is unknown. This is risk. Think of this as going to Vegas and gambling. Before you set foot at the table, all of the outcomes are known as are the probabilities of each. No outcome surprises an objective third party.
3. Outcomes are unknown and probabilities are unknown. In this case, the distribution of outcomes are unknown and the individual outcomes are necessarily unknown. This is uncertainty.

We often think we're making decisions in #2 but we're really operating in #3. The difference may seem trivial but it makes a world of difference.

Decisions Under Uncertainty

Ignorance is a state of the world where some possible outcomes are unknown: when we've moved from #2 to #3.

One way to realize how ignorant we are is to look back, read some old newspapers, and see how often the world did something that wasn't even imagined.

Some examples include the Arab Spring, the collapse of the Soviet Union, the financial meltdown.

We're prepared for a world much like #2 — the world of risk, with known outcomes and probability that can be estimated, yet we live in a world with a closer resemblance to #3.

72. The Two Types of Ignorance

The first category of ignorance is when we do not know we are ignorant. This is primary ignorance. The second category of ignorance is when we recognize our ignorance.

This article builds on Decisions Under Uncertainty. In fact, consider this a continuation. Think of how we make decisions in organizations — we often do what standard decision theory would ask of us.

We create a powerpoint that identifies the future desired state, identify what might happen, attach weighted probabilities to outcomes, and make a choice. Perfectly rational. Right? One of the problems with this approach is the risk charts and matrices that accompany this analysis.

In my experience, these charts are rarely discussed in detail and become more about checking the ‘I thought about risk’ box than anything else. We conveniently pin things into categories of low, medium, or high risk with a corresponding “impact” scale.

What gets most of the attention is high-risk, high-impact. Perhaps deservedly so. But you have to ask yourself, how did we arrive at these arbitrary scales? Is one person’s look at risk the same as someone else’s? Are there hidden incentives to nudge risk one way or another? What biases come into play?

Often we can’t even identify everything. Rarely do people ever go back and look at what happened and how accurate those “risk” tables were. From the ones I’ve seen, the “low risk” stuff happens a lot more often than people imagined. And a lot of things happen that never even made the chart in the first place.

On the occasion when people do go back, and I’ve seen this firsthand, hindsight bias creeps in. “Oh, we discussed that, but it didn’t make it in the document. But we knew about it.” Yes, of course, you did.

Ignorant and Unknowing

We’re largely ignorant, that is, we operate in a state of the world where some possible outcomes are unknown. However, we’ve prepared for a world where outcomes and probabilities can be estimated. There is a mismatch between our training and reality. You can’t even hope to accurately estimate probabilities if the range of outcomes is unknown.

The Two Types of Ignorance

The first category is when we do not know we are ignorant. This is primary ignorance. The second category is when we recognize our ignorance. This is called recognized ignorance. Empty Suits and Fragilistas are almost always ignorant and unknowing.

In Antifragile, Nassim Taleb writes:

[The Empty Suit/Fragilista] defaults to thinking that what he doesn’t see is not there, or what he does not understand does not exist. At the core, he tends to mistake the unknown for the nonexistent.

That my friends is primary ignorance. And it’s not limited to empty suits and fragilistas.

Consider Anna Karenina:

Primary ignorance ruins the life of one of fiction’s most famous characters, Anna Karenina. Readers of Anna Karenina (1877/2004) know that, in this novel, a train bookends bad news. Anna alights from one train as the novel begins and throws herself under another one as it ends. As she enters the glittering world of pre-Revolutionary Saint Petersburg, Anna catches the eye of the aristocratic bachelor Count Vronsky and quickly falls under his spell. But there is a problem: she is married to the rising politician Karenin, the two have a son Seryozha, and society will not take kindly to the conspicuous adultery of a prominent citizen. Indulging in an extra-marital affair, especially when one’s husband is a respected member of society, promotes the likelihood of unpleasant (events). But her passion for Vronsky dulls Anna’s capacities for self-awareness. She becomes pregnant out of wedlock, a disastrous condition for a woman in nineteenth-century Russia. Anna

consistently displays an unfortunate propensity to take action without recognizing that a terrible consequential outcome is possible. That is, she operates in primary ignorance. Anna demonstrates all the characteristics of primary ignorance. She fails to consider all the possible scenarios that will occur from her impulsive decision making. She risks her marriage with Karenin, a kind if undemonstrative husband, who is willing to forgive and even offers to raise her illegitimate child as his own. Leaving Seryozha with Karenin, she and Vronsky escape to Italy and then to his Russian country estate. Ultimately, she finds that while Vronsky continues to be accepted socially, living his life exactly as he pleases, the door of society slams shut in her face. No one will associate with her and she is insulted as an adulterer wherever she goes. It is only when she is completely isolated socially and cut off from her beloved son that Anna recognizes the dangers of primary ignorance: she risked her family and her reputation for too little. ... She realizes she was ignorant of the possible outcomes that jumping headlong into an illicit relationship would bring.

Ignorance, primary or recognized, is only important if the expected consequences are significant. Otherwise, we can be ignorant without consequence.

While human irrationality factors into all decisions, it hits us most when we are unknowingly ignorant.

Rational decision making becomes harder as we move along the continuum: outcomes are known → risk → uncertainty/ignorance.

If we can not consider all possible outcomes, preventing failure becomes nearly impossible. Further complicating matters, situations of ignorance often take years to play out. Joy and Zeckhauser write:

One could argue ... that a rational decision maker should always consider the possibility of ignorance, thus ruling out primary ignorance. But that is a level of rationality that very few achieve.

If we could do this we'd always be in the space of recognized ignorance, better, at least, than primary ignorance.

"Fortunately," write Joy and Zeckhauser, "there is a group of highly perceptive chroniclers of human decision-making who observe individuals and follow their paths, often over years or decades. They are the individuals who write fiction: plays, novels, and short stories describing imagined events and people (or fictional characters.)"

Joy and Zeckhauser argue these works have "deep insights" into the way we approach decisions, "both great and small."

In the Poetics, a classical treatise on the principles of literary theory, Aristotle argues that art imitates life. We refer here to Aristotle's ideas of mimesis, or imitation. Aristotle claims one of art's functions is the representation of reality. "Art" here includes creative products of the human imagination and, therefore, any work of fiction. Indeed, a crevice, not a canyon, separates fact and fiction.

For centuries, authors have attempted to depict situations of ignorance. In Greek literature, Sophocle's King Oedipus and Creon, and Homer's Odysseus all seek forecasting skills of the blind prophet Tiresias who is doomed by Zeus to "speak the truth no man may believe."

For its status as one of literature's most enduring love stories, Jane Austen's Pride and Prejudice begins rather unpromisingly: the hero and the heroine cannot stand each another. The arrogant Mr. Darcy claims Elizabeth Bennet is "not handsome enough to tempt me"; Elizabeth offers the equally withering riposte that she "may safely promise ... never to dance with him." Were we to encounter them after these early skirmishes, we (like Elizabeth and Darcy themselves) would be ignorant of the possibility of an ultimate romance.

In Gustave Flaubert's Madame Bovary (1856/2004), Charles Bovary is a stolid rural doctor who is ignorant of the true character of the woman he is marrying. Dazzled by her youth

and beauty, he ends up with an adulterous wife who plunges him into debt. His wife Emma, the titular “Madame Bovary,” is equally ignorant of the true character of her husband. Her head filled with romantic fantasies, she yearns for a sophisticated partner and the glamor of city life, but finds herself trapped in a somnolent marriage with a rustic man.

K., the land surveyor and protagonist of Franz Kafka’s The Castle, attempts, repeatedly and unsuccessfully, to gain access to the mysterious authorities of a castle but is frustrated by an authoritarian bureaucracy and by ambiguous responses that defy rational interpretation. He begins and ends the novel (as does the reader) in ignorance.

Joy and Zeckhauser use stories to study ignorance, which makes sense.

Stories offer “simulations of the social world,” according to Psychologists Raymond Mar and Keith Oatley, through abstraction, simplification, and compression. Stories afford us a kind of flight simulator. We can test run new things and observe and learn, with little economic or social cost. Joy and Zeckhauser believe “that characters in great works of literature reproduce the behavioral propensities of real-life individuals.”

While we’ll likely never uncover situations as fascinating as we find in stories, this doesn’t mean they are not a useful tool for learning about choice and consequence.

“In a sense,” Joy and Zeckhauser write, “this is why great literature will never get dated: these stories observe the details of human behavior, and present such behavior awash with all the anguish and the splendor that is the lot of the human predicament.

As Steven Pinker notes in How The Mind Works:

Characters in a fictitious world do exactly what our intelligence allows us to do in the real world. We watch what happens to them and mentally take notes on the outcomes of the strategies and tactics they use in pursuing their goals.

If we assume, we live in a world where we are, to some extent, ignorant then the best course is “thoughtful action or prudent information gathering.” Yet, when you look at the stories, “we frequently act in ways that violate such advice.”

So reading fiction can help us adapt and deal with the world of uncertainty.

73. Avoiding Ignorance

This is a continuation of two types of ignorance.

You can't deal with ignorance if you can't recognize its presence. If you're suffering from primary ignorance, it means you probably failed to consider the possibility of being ignorant or you found ways not to see that you were ignorant.

You're ignorant and unaware, which is worse than being ignorant and aware.

The best way to avoid this suggests Joy and Zeckhauser, is to raise self-awareness.

Ask yourself regularly: "Might I be in a state of consequential ignorance here?"

They continue:

If the answer is yes, the next step should be to estimate base rates. That should also be the next step if the starting point is recognized ignorance.

Of all situations such as this, how often has a particular outcome happening? Of course, this is often totally subjective.

and its underpinnings are elusive. It is hard to know what the sample of relevant past experiences has been, how to draw inferences from the experience of others, etc.

Nevertheless, it is far better to proceed to an answer, however tenuous, than to simply miss (primary ignorance) or slight (recognized ignorance) the issue. Unfortunately, the assessment of base rates is challenging and substantial biases are likely to enter.

When we don't recognize ignorance, the base rate is extremely underestimated. When we do recognize ignorance, we face "duelling biases; some will lead to underestimates of base rates and others to overestimates."

Three biases come into play while estimating base rates: overconfidence, salience, and selection biases.

So we are overconfident in our estimates. We estimate things that are salient – that is, "states with which (we) have some experience or that are otherwise easily brought to mind." And "there is a strong selection bias to recall or retell events that were surprising or of great consequence."

Our key lesson is that as individuals proceed through life, they should always be on the lookout for ignorance. When they do recognize it, they should try to assess how likely they are to be surprised—in other words, attempt to compute the base rate. In discussing this assessment, we might also employ the term "catchall" from statistics, to cover the outcomes not specifically addressed.

It's incredibly interesting to view literature through the lens of human decision making.

Crime and Punishment is particularly interesting as a study of primary ignorance.

Raskolnikov deploys his impressive intelligence to plan the murder, believing, in his ignorance, that he has left nothing to chance. In a series of descriptions not for the squeamish or the faint-hearted, the murderer's thoughts are laid bare as he plans the deed. We read about his skills in strategic inference and his powers of prediction about where and how he will corner his victim; his tactics at developing complementary skills (what is the precise manner in which he will carry the axe?; what strategies will help him avoid detection) are revealed.

But since Raskolnikov is making decisions under primary ignorance, his determined rationality is tightly "bounded." He "construct[s] a simplified model of the real situation in order to deal with it; ... behaves rationally with respect to this model, [but] such behavior is not even approximately optimal with respect to the real world" (Simon 1957). The second-guessing, fear, and delirium at the heart of Raskolnikov's thinking as he struggles to gain a foothold in his inner world show the impact of a cascade of Consequential Amazing Development's (CAD), none predicted, none even contemplated. Raskolnikov anticipated an outcome in which he would dispatch the pawnbroker and slip quietly out of her apartment. He could not have possibly predicted that her sister would show up, a characteristic CAD that challenges what Taleb (2012) calls our "illusion of predictability."

Joy and Zeckhauser argue we can draw two conclusions.

First, we tend to downplay the role of unanticipated events, preferring instead to expect simple causal relationships and linear developments. Second, when we do encounter a CAD, we often counter with knee-jerk, impulsive decisions, the equivalent of Raskolnikov committing a second impetuous murder.

74. Your Product is Decisions

If you asked people what they produce on a daily basis, most would say email or meetings. Even the ones who offered a deeper answer would probably think of these first. It is natural to think this way if you're a knowledge worker. Natural and incorrect. In a conversation with journalist Jason Zweig, Nobel Laureate Daniel Kahneman argues that knowledge workers produce decisions. And the quality of those decisions varies widely.

(At many financial institutions) the product is decisions. They produce decisions. And there ought to be something that is equivalent to the quality control you find in manufacturing. Now you can't control the product itself; test the product. But you can test the process by which the product was created. So there are questions you can ask about the process by which a judgment was made or a decision was made. And one of these aspects is going to be the quality and quantity of the information on which the judgment was based. And if you isolate that as one of the issues you are going to focus on, it's not the quality of the story you can make, it's actually 'Where does the evidence come from?', 'What do we really know?' It's when you ask those questions that you work out that, actually, you know very little and that you told yourself a coherent story on the basis of inadequate information.

Kahneman doesn't feel individuals can go back and objectively assess their own decisions. This is, however, something organizations can do. Most, however, will choose not to because it is too painful.

Most organizations don't use a consistent process or framework to make important decisions. Yet we know that the process by which you come to a decision is the most important thing. It's not about more information. Process matters more than the analysis. We also know that when you don't use a consistent process you make it hard to improve. If your product is decisions, you might be curious as to how we can improve our ability to make them::

1. Know your circle of competence. This is how Ted Williams excelled.
2. When operating within your circle of competence, use a double filter for making decisions.
3. Avoid using vague and ambiguous terms.
4. Keep a decision journal.
5. Ignore outcome when evaluating decisions.

Kahneman's book, Thinking, Fast and Slow, is a must-read.

75. How to Make Smart Decisions Without Getting Lucky

Few things will change your trajectory in life or business as much as learning to make effective decisions. Yet no one really teaches us what it means to make consistently high-quality decisions.

The decision-making principles in this article are both practical and time-tested. They work in the real world.

In this guide, we'll cover:

- [No One Taught you How to Decide](#)
- [Your Mind is a Pattern Matching Machine](#)
- [Decision Making](#)
- [Smart People Make Terrible Decisions](#)
- [Sources of Stupidity](#)
- [Intelligent Preparation: The World Is Multidisciplinary](#)
- [How We Make Decisions](#)
- [General Thinking Concepts](#)
- [Add To Your Decision-Making Skills](#)
- [Books to Improve Decisions](#)

Ready? Ok, Let's dig in.

No one Taught you How to Decide

I started working at an intelligence agency on August 28, 2001. Two weeks later, the world would never be the same.

My computer science degree lost its value after a few promotions. I came from a world of 1s and 0s, not people, families, and interpersonal dynamics.

Just out of school, I found that my decisions affected not only my employees but their families. Not only my country but other countries. However, there was one small problem. I had no idea how to make smart decisions. I had no idea how to reduce errors. I only knew I had an obligation to make the best decisions I could. But where do you start?

There is no class called "decision making." Making better decisions isn't one skill but rather a series of tools and frameworks. What distinguishes consistently good decision-makers from poor ones is a series of diverse mental frameworks and tools (as well as relevant specific information).

Most of us operate like a carpenter with only a hammer. To a man with a hammer, every problem looks like a nail. No matter the job, we pull out our hammer and attempt to make it work. While a hammer can often get the job done eventually, it comes with a cost. In my world, a poor decision could cost lives, impact my country, or even start a war. A hammer wasn't enough, I wanted more tools.

"The older I get the more I realize how many kinds of smart there are. There are a lot of kinds of smart. There are a lot of kinds of stupid, too."

— JeFF Bezos

To fill my mental toolbox, I looked around my organization and found some mentors. I watched them, asked them annoying questions, and tried to learn as much as I could from them. I went back to school to get an MBA. I read everything I could about making decisions and the tools I needed to develop.

Thanks to the internet, I was no longer limited to the best teachers in my organization or university. The entire world was available. I could find the best teachers in the world, learn their tools and frameworks, and add them to my mental toolbox.

Pattern Matching

You probably don't know it but you already think in mental models. Mental models are mental chunks of knowledge that represent a concept. Gravity is a model. So are probabilistic thinking, inversion, and entropy.

Mental models shape how you think, how you approach problems, and how you identify the information that matters and ignore what doesn't. The mental models in your head are your cognitive skillset.

Decision Making

Think about the state of your life, your career, your business, your major relationships — anything consequential to you.

How many important decisions have you already had to make? With the benefit of hindsight, how well did you make them?

How many decisions did you make today? How did you make these decisions? Is there a better way?

Not all decisions matter. Most decisions, like where to grab a sandwich, are unimportant. The consequences of these decisions don't matter.

Yet some decisions are critical — they change our lives. Whether its who to trust, where to live, or whom to marry, these decisions reverberate for years.

Yet most of us don't have the right skills to think through these problems. As a result, we often fall back to the pro-con list, where you list all the positive things that happen on one side and the negative things on the other trading them off.

While useful when deciding what to have for lunch, the pro-con list comes with a lot of blind spots.

"I regard it as a criminal waste of time to go through the slow and painful ordeal of ascertaining things for one's self if these same things have already been ascertained and made available by others."

— Thomas Edison

SMART People Make Terrible Decisions

Otherwise smart people can make terrible decisions. Think about decisions like these:

- Napoleon decided to invade Russia (and Hitler did it again 130 years later)
- An editor deciding to publish O.J Simpson's *If I Did It*

- Chris Webber choosing the timeout he didn't have in the 1993 Final Four
- NASA's decision to ignore the O-ring issues on the Challenger
- President Kennedy's famous blunder to continue the Bay of Pigs operation inherited from the previous administration (a mistake he quickly learned from)
- Margaret Thatcher deciding to get behind a "poll tax" that led to her ouster by her own party
- Juergen Schrempp, the CEO of Daimler-Benz, deciding to merge with Chrysler despite massive internal opposition and general history of big M&A deals working very poorly
- Jim Cramer looking at Bear Stearns in 2007 and calling it a "BUY"
- ...and a hundred thousand more...

These were catastrophic decisions made by people who were, in some sense, professional decision-makers. They had impeccable credentials and judgment, and yet they made poor decisions due to poor judgment, a too-limited mental representations of the world, or just plain stupidity.

Sources of Stupidity

There are a lot of reasons we fail to make effective decisions.

Let's take a look at five of the biggest ones:

1. We're unintentionally stupid. I like to think that I'm rational and capable of interpreting all information in a non-biased way but that's a dream. Cognitive biases are great at explaining how our evolutionary programming leads us astray. Knowledge of these biases in advance rarely helps us make better decisions. There are, however, many easily recognizable situations that increase the odds we're about to do something stupid. Whether we're tired, overly focused on a goal, rushing, distracted, operating in a group, or under the influence of a group, we're more prone to stupidity.²
 2. We have the wrong information. Making decisions with the wrong assumptions or facts is likely to lead to disaster.
 3. We use the wrong model. We use mental models to make decisions. The quality of those models determines the quality of our thinking. There are a variety of reasons that we use false, incomplete, or incorrect models. Novices are prone to using models that the expert knows are incomplete or irrelevant. The odds of employing the wrong models increase as the pace of environmental change increases.
 4. We fail to learn. We all know the person that has 20 years of experience but it's really the same year over and over. Well, that person is sometimes us. If we don't understand how we learn, we're likely to make the same mistakes over and over.
 5. Looking over doing good. Our evolutionary programming conditions us to do what's easy over what's right. After all it's often easier to signal being virtuous than actually being virtuous. We unconsciously make choices based on optics, politics, and defendability. We hate criticism and seek the validation of our peers and superiors. We often want to feel good about ourselves first and have the outcome we desire second.
- Luckily, we can take steps to reduce the odds of stupidity and increase the odds of good decisions in each of these categories.

"The frog in the well knows nothing of the mighty ocean."

— Japanese Proverb

Intelligent Preparation: The World Is Multidisciplinary

We live in a society that demands specialization. Being the best means being an expert in something. Letters after your name and decades in the trenches of experience are required before you can claim to know anything. In one sense there is nothing wrong with this — specialized knowledge is required to solve problems and advance our global

potential. But a byproduct of this niche focus is that it narrows the ways we think we can apply our knowledge without being called a fraud.

So we think physicists can't teach us about love; mathematicians can't instruct us on how to run a business; poets don't know squat about "my life." And bloggers can't contribute to philosophy.

I don't believe this is true.

Knowledge is hard to come by.

It takes work and commitment, and I think we owe it to ourselves to take it out of the box it comes in and experiment with it. We should blow past conformity and apply all the knowledge at our disposal to the problems and challenges we face every day.

Think about it. Over time you've picked up a lot of fundamentals about how the world works. You may have read a book about the Manhattan Project and the building of the nuclear bomb that was launched at Hiroshima. This story conveys the awesome power of self-sustaining nuclear reactions. Have you ever thought about applying those ideas to your life? You should.

How We Make Decisions

When was the last time you thought about how you make decisions?

If you're like most people, you've never been explicitly taught how to make effective decisions. You make decisions like a golfer who never took any lessons: miserable with the state of your game and yet not seeking to learn a better swing, and instead hoping for the best every time you lift the club. Hoping that this time your choice will finally work out. In the early 1980s, Charlie Munger and his partner Warren Buffett realized that a Savings & Loan operation they owned, as with the rest of the industry, was doomed to fail miserably due to forces outside of their control. At a time when almost none of their peers were taking action, they changed course dramatically, massively reducing the effect of the bank's failure on the rest of their business holdings. These two men knew they had to act much differently than their peers.

It worked: The S&L industry collapsed, yet Munger and Buffett escaped with barely a scratch. They saved themselves a great deal of stress and financial pain by applying a uniquely effective system of organized common sense. In hindsight, it seems like an obvious good decision; at the time, it seemed odd and unusual.

The lesson for us is that the people making consistently good decisions take advantage of how the world works. That's wisdom.

Real knowledge of the art of decision making, which remains true across time and circumstances, eras and epochs, can help increase the odds that we get what we want and reduce costly mistakes.

While everyone else is guessing, falling into old patterns, blindly following cognitive biases, we can be clear-headed and laser-focused.

That's what Farnam Street is all about.

Here are some examples of applying — or failing to apply — knowledge about how the world really works.

- It doesn't matter how smart you are if you don't realize where things are additive and where they are multiplicative. Nikola Tesla failed to understand Multiplication by Zero when he failed to realize that poor relations with others affected his life. While the Serbian-American was a brilliant inventor, he had difficulty relating to others, which made him difficult to work with. This problem cost him a Nobel Prize and a fortune that today would likely have made him the richest man in the world.
- While we all rely on maps, which are reductions of complexity, to make decisions, they are not always accurate. General George S. Patton Jr. understood that the map is not the territory. When he visited the troops near Coutances, he found them sitting on the side of the road, studying a map. Responding to Patton's inquiry as to

why they had not crossed the Seine, the troops informed him that they were studying the map and could not find a safe place to wade across. Patton informed them that he had just waded across it and it was not more than two feet deep.

- While we all like to be in the sexy industries, that desire shows an under-appreciation for the laws of thermodynamics. Smart companies like Berkshire Hathaway, guided by legendary investor Warren Buffett, understand that contrast is important. Sexy internet businesses are rarely effective, no matter how good they are, because the others are nearly just as good. What you want is contrast — to be the big fish in a small pond. And when you analyze the types of investments he's made over the years, that's what you find. If you're going to compete with people, you want to compete with people who are way less sophisticated than you.
- Understanding and applying the mental model of relativity helped Michael Abrashoff take the worst-performing ship in the US Pacific Fleet and turn it into the best. In his book, *It's Your Ship*, he wrote: "The most important skill a skipper can have is the ability to see through the eyes of the crew."

This website is about understanding and applying these time-tested mental models. Knowing how the world works means that you can stop fighting reality — and yourself along with it.

General Thinking Concepts

Combining intelligent preparation — learning about the big time-tested ideas from multiple disciplines — with general thinking frameworks will dramatically improve your decision-making skills.

These thinking frameworks help you look at problems through different lenses.

- Inversion — Otherwise known as thinking something through in reverse or thinking "backwards," inversion is a problem-solving technique.
- Second-Order Thinking — Ask yourself, "And then what?"
- The Map Is Not the Territory — The map of reality is not reality itself. If any map were to represent its actual territory with perfect fidelity, it would be the size of the territory itself.

All of these concepts (and six others) can be found in *The Great Mental Models Volume 1: General Thinking Concepts*.

76. Just In Time Information Gathering

We're becoming more like factories.

Just-in-time is a production strategy aimed at, among other things, reducing the need for excess inventory. Parts are supplied only when needed in the amount needed. While it makes a business more capital efficient, it also makes it more fragile.

We've adopted a similar strategy for information gathering. We're so consumed by noise and busy work that the only time we really seek out signal is when we need it the most: right before we make a decision.

This creates a host of problems.

The worst time to look for information is when we need it to make a decision. When we do that we're more likely to see what's unique and miss the historical context. We're also more likely to be biased by what is available. And searching for information at the time of need is an indication that you have no idea what you're doing.

"Pattern recognition," says Alice Schroeder, "creates an impulse always to connect new knowledge to old and to primarily be interested in new knowledge that genuinely builds on the old." It helps knowledge snowball.

If we can't connect the current situation to something we already understand, we might reason that it is not in our circle of competence and thus we shouldn't be drawing conclusions. If we can, however, connect it to something we previously understood then we're less likely to draw conclusions on the basis of "this time is different."

There is merit to thinking about information gathering as a logistics problem.

77. Daniel Kahneman's Favorite Approach For Making Better Decisions

Bob Sutton's book, *Scaling Up Excellence: Getting to More Without Settling for Less*, contains an interesting section towards the end on looking back from the future, which talks about "a mind trick that goads and guides people to act on what they know and, in turn, amplifies their odds of success."

We build on Nobel winner Daniel Kahneman's favorite approach for making better decisions. This may sound weird, but it's a form of imaginary time travel.

It's called the premortem. And, while it may be Kahneman's favorite, he didn't come up with it. A fellow by the name of Gary Klein invented the premortem technique.

A premortem works something like this. When you're on the verge of making a decision, not just any decision but a big decision, you call a meeting. At the meeting, you ask each member of your team to imagine that it's a year later.

Split them into two groups. Have one group imagine that the effort was an unmitigated disaster. Have the other pretend it was a roaring success. Ask each member to work independently and generate reasons, or better yet, write a story, about why the success or failure occurred. Instruct them to be as detailed as possible, and, as Klein emphasizes, to identify causes that they wouldn't usually mention "for fear of being impolite." Next, have each person in the "failure" group read their list or story aloud, and record and collate the reasons. Repeat this process with the "success" group. Finally use the reasons from both groups to strengthen your ... plan. If you uncover overwhelming and impassible roadblocks, then go back to the drawing board.

Premortems encourage people to use "prospective hindsight," or, more accurately, to talk in "future perfect tense." Instead of thinking, "we will devote the next six months to implementing a new HR software initiative," for example, we travel to the future and think, "we have devoted six months to implementing a new HR software package."

You imagine that a concrete success or failure has occurred and look "back from the future" to tell a story about the causes.

[...]

Pretending that a success or failure has already occurred—and looking back and inventing the details of why it happened—seems almost absurdly simple. Yet renowned scholars including Kahneman, Klein, and Karl Weick supply compelling logic and evidence that this approach generates better decisions, predictions, and plans. Their work suggests several reasons why. ...

1. This approach helps people overcome blind spots

As ... upcoming events become more distant, people develop more grandiose and vague plans and overlook the nitty-gritty daily details required to achieve their long-term goals.

2. This approach helps people bridge short-term and long-term thinking

Weick argues that this shift is effective, in part, because it is far easier to imagine the detailed causes of a single outcome than to imagine multiple outcomes and try to explain why each may have occurred. Beyond that, analyzing a single event as if it has already occurred rather than pretending it might occur makes it seem more concrete and likely to actually happen, which motivates people to devote more attention to explaining it.

3. Looking back dampens excessive optimism

As Kahneman and other researchers show, most people overestimate the chances that good things will happen to them and underestimate the odds that they will face failures, delays, and setbacks. Kahneman adds that "in general, organizations really don't like pessimists" and that when naysayers raise risks and drawbacks, they are viewed as "almost disloyal."

Max Bazerman, a Harvard professor, believes that we're less prone to irrational optimism when we predict the fate of projects that are not our own. For example, when it comes to friends' home renovation projects, most people estimate the costs will run 25 to 50 percent

over budget. When it comes to our projects; however, they will be “completed on time and near the project costs.”

4. A premortem challenges the illusion of consensus

Most times, not everyone on a team agrees with the course of action. Even when you have enough cognitive diversity in the room, people still keep their mouths shut because people in power tend to reward people who agree with them while punishing those who dare to speak up with a dissenting view.

The resulting corrosive conformity is evident when people don't raise private doubts, known risks, and inconvenient facts. In contrast, as Klein explains, a premortem can create a competition where members feel accountable for raising obstacles that others haven't. “The whole dynamic changes from trying to avoid anything that might disrupt harmony to trying to surface potential problems.”

78. The Default-Thinking Method of Problem Solving

You've been here before. It's Monday morning and you walk into the office only to have your boss call an urgent meeting to "streamline processes." You haven't thought about this enough to have an opinion but you go anyway.

You know how to deal with this. You've done it before. You turn on your default brain and start solving the problem. You build a hypothesis to determine the problem, find some data to analyze, and presto out comes some efficiency.

Most of the time this works well enough, but not always. Sometimes—more often than we'd like to admit—things change: markets shift and consumers behave in unpredictable ways. Now we're rudderless.

In the wonderful book *The Moment of Clarity: Using the Human Sciences to Solve Your Toughest Business Problems*, the authors write:

We are forever in the midst of change, but not all of it is seismic. It's vital for a business to understand the difference between the uncertainties present on an average day and the uncertainties of a major cultural shift. ... Business issues can be categorized along a problem scale within three levels of complexity. This framework is useful for distinguishing very complex problems from those that are actually manageable.

The Three Levels of Business Problems

1. *A clear-enough future with a relatively predictable business environment. You know what the problem is, and you can apply a proven algorithm to fix it. "If I invest \$ 1 in media spending for advertising, I know that I will get something like \$ 1.5 back because of market stimulation." "The industry has average admin costs of 8 percent of total revenue. Mine are 10 percent. We should cut that back."*

2. *Alternative futures with a set of options available. You have a feel for the problem and might have seen something like it before. It makes sense to test your hunch as a hypothesis. For example, "Our sales numbers are down even when we invest in more salespeople, but we have seen the same pattern in the European Union and China. We might be hiring too many new salespeople too quickly and expecting them to deliver the same payback that the existing salespeople are delivering."*

3. *High level of uncertainty, with no understanding of the problem. You simply don't know what the problem is, let alone the solution. You can see that something is wrong, but have no clear idea about what to do. For example, "Our media division is losing business to internet start-ups," "We are investing more in customer service, but our customers are becoming increasingly dissatisfied with us," and "We are designing products that seem right for the marketplace, but the marketplace isn't interested."*

Most of our problems tend to be in 1 or 2. Uncertainty, remember, happens when we fail to know the range of possible outcomes (and, correspondingly, their probabilities.) These are really messy problems.

Solving the problems of 1 and 2 are generally much easier. We use default thinking.

The default problem-solving model has its roots in what can be called instrumental rationalism. At the heart of the model is the belief that business problems can be solved through objective and scientific analysis and that evidence and facts should prevail over opinions and preferences. To get to the right answer, so the thinking goes, you should adhere to the following principles of problem solving:

1. *All business uncertainties are defined as problems. Something in the past caused the problem, and the facts should be analyzed to clarify what the problem is and how to solve it.*

2. *Problems are deconstructed into quantifiable and formal problem statements (issues). For example, "Why is our profitability falling?"*

3. *Each problem is atomized into the smallest possible bits that can be analyzed separately—for example, breaking down the causes of profitability into logical issues. This*

analysis would include “issue trees” for all the hundreds of potential levers for either decreasing costs or growing revenue (customer segments, markets, market share, price, sales channels, operations, new business development, etc.)

4. A list of hypotheses to explain the cause of the problem is generated. For example, “We can increase profitability by lowering the cost of our operations.”

5. Data is gathered and processed to test each hypothesis— all possible stones are turned and no data source is left untouched.

6. Induction and deduction are used to test hypotheses, clarify the problem, and find the areas of intervention with the highest impact, or what is commonly called “bang for the buck.”

7. A well-organized structure of the analysis is deployed to build a logical and fact-based argument of what should be done. The structure is built like a pyramid that develops the supporting facts, some subconclusions, and an overall conclusion and then ends with a prioritized list of interventions to which the company should adhere.

8. All proposed actions are described as manageable work streams or must-win battles for which a responsible committee, or person, is assigned.

9. Performance metrics and a proposed time frame with follow-up monitoring are put in place for each committee to complete the task.

10. When all work streams have been completed, the problem is solved.

When done correctly by competent people, this can be a thing of beauty. This is, in part, why we hire consultants like myself, McKinsey, or Bain. We believe they can solve any problem. The idea that management is a type of science with a repeatable formula in the face of any problem is not a new idea. “It can be traced back to the nineteenth century, when positivism, the prevalent philosophy of the day, argued that you could objectively measure reality.” The founding father of the idea of management science, if there was one, Frederick Winslow Taylor.

Taylor left a prestigious education at Harvard to work at steel companies throughout Pennsylvania. Whereas most manufacturing and factory plants had cobbled together their organization through rules of thumb and common sense, Taylor was the quintessential positivist, seeking scientifically validated measurements, or properties. He followed workers, clicking his stopwatch every time they started and stopped, measuring the time it took to complete each discrete action of hauling their large iron ore loads. Through his enormously successful tenure at steel companies, he extracted generalized principles of management that he used to create the world’s first business case study. It wasn’t long before a partnership between Harvard’s School of Applied Science and its brand-new business school came calling. Might Taylor bring together his experience into something the school could teach its young students about productivity? Taylorism, based on the following premise, was born:

To work according to scientific laws, the management must take over and perform much of the work which is now left to the men; almost every act of the workman should be preceded by one or more preparatory acts of the management which enable him to do his work better and quicker than he otherwise could.

Today’s problems seem infinitely more complex than counting iron ore hauls and yet we still attack them with the same general approach of Taylorism. This is what most MBAs, including mine, taught: people work harder with the right incentives, optimize and perfect workflow, analyze every movement looking for efficiencies, remove discretion when possible because that creates variance, etc. Of course we’ve evolved Taylorism, today we call it “lean” and “six sigma” and whatever else.

For most of us, default thinking is so familiar to us— the very air we breathe— that we are no longer able to explain it or even to see it. For that reason, if we really want to understand why we continue to get people wrong, we need to unpack the fundamental assumptions that make up the culture of most of our days.

Is this really how we approach problems? What are the assumptions we're making when we take this approach?

Assumption 1: People Are Rational And Fully Informed

One of the unintentional consequences of solving problems by testing logical hypotheses is that you are forced to assume that people are rational decision makers: aware of their needs, fully informed of all their choices, and capable of making the best choice. The reason is simple: it is very difficult to test a hypothesis about things that you can't measure objectively. It's even harder to test something that is deeply personal, cannot be decoded into explicit descriptions, and requires a lot of interpretation. Think about the question "Are you a good parent?" or "Do you have good taste?"

A simple answer misses most of what matters about parenting and good taste. To deal with this problem, companies base their problem solving on what can objectively be described, quantified, and analyzed without too much interpretation.

So we default to measuring perceptions and desires, more specifically, we end up with people's perceptions of reality. There is nothing wrong with this but it is limited and we should be aware of its limitations. These are not the only two aspects of humanity that matter. And even if they were, the way default thinking solves problems rarely offers us any understanding of how they work. We find some spurious relationship and assume causation when, in reality, it's merely a correlation. When it changes we have no idea why. We're more complex than that.

Most recent studies evaluating how people buy reveal us to be far more chaotic creatures. We rarely know what we want. We almost never fully grasp the market and, most important, we almost always buy something at a different price than what we thought we would. Even studies of people with written shopping lists (milk, eggs, apples, etc.) reveal that they find themselves far astray from their original intentions once they reach the grocery store.

We do this because intentions are relatively easy to study. But as Dr. House says, "everybody lies."

People think they cook a lot, but they really don't. It's not that they want to lie to other people; they are simply lying to themselves.

There is often a wealth of distance between what people say and what people do.

It's not that people don't care about anything. They just don't care as much as most companies assume that they do. And most often, people couldn't care less. When they buy one kind of chocolate bar rather than another, it is rarely because they have a strong brand preference. More often than not, it is because the chocolate was closer on the counter, it had a color that fit the mood, or it simply came packaged as a "two for one." The good news for companies is that we buy a lot of stuff. The bad news is that we don't always know why.

Assumption 2: Tomorrow Will Look Like Today

A good example of this attitude can be found in a 2006 article in the McKinsey Quarterly. In identifying trends that will shape the business environment, the article says that management itself will shift from an art to a science:

Long gone is the day of the "gut instinct" management style. Today's business leaders are adopting algorithmic decision-making techniques and using highly sophisticated software to run their organizations. Scientific management is moving from a skill that creates competitive advantage to an ante that gives companies the right to play the game.

We're bombarded with the word "science."

When thought leaders use the word science to describe a business discipline like marketing, retail design, negotiation skill, or strategy, we are led to believe that these disciplines can be predicated on scientific truths. Does the science of shopping have the same universal laws as Darwin's theory of natural selection?

This is part of the reason we trick ourselves.

Rarely do we have to ask, “Where does the hypothesis come from?” But by assuming that the hypothesis is based on some kind of universal law, we fool ourselves into believing that the assumptions of the current moment will also hold true in the future. In these situations, the idea that management is a kind of natural science blinds us rather than enlightens us.

Assumption 3: Hypotheses are Objective and Unbiased

Here is a great example:

In the toy industry, the dominating idea is that children have a short attention span and need toys that stimulate their desire for instant traction. A toy, it is assumed, must grab the attention of the child in the store, and he or she should not need any skills to play with it. Another assumption is that physical toys are losing ground to digital toys because the former are too tedious and not stimulating enough.

In reality, when you study children—and if you read the majority of academic literature about children—you will probably reach the opposite conclusion: children are highly motivated by play experiences that require skill and mastery and that can give them a sense of hierarchy and accomplishment. Digital play is gaining in popularity precisely because it requires a very sophisticated skill set; it can be played for thousands of hours and it gives the players clear feedback with levels and hierarchies.

Over time, companies and people create “commonsense” ideas about the world and how it works. We take things as given and rarely challenge them.

*The French anthropologist Pierre Bourdieu coined the term *habitus* to describe the somehow hidden but always present dispositions that shape our perceptions, thoughts, and actions. In his view, many things that we regard as common sense are in fact shaped by the social context we are in. Over time we learn what is normal and taken as a given through our social interaction with the world—our family, our society, our friends, our work—and our perceptions become a kind of automatic understanding of the world. This understanding enables us to act normally without really thinking about it. Over time, companies similarly create commonsense ideas about the world. Certain things are simply taken as a given, no longer contested: for example, the idea that designers and engineers will never see eye-to-eye, or that open offices provide more opportunities for collaboration. This is one reason consultants can be effective, they come in with a different understanding and offer opinions—intentionally or not—that challenge some of these commonsensical views.*

In terms of default thinking:

A company might think that it has created an objective set of possible hypotheses to test. But in reality each hypothesis is always based on something. Very often, that thing is a product of culture, not of science. And once our assumptions are firmly rooted in our cultural understanding, they have a way of becoming ever more entrenched.

Then confirmation bias kicks in. We look for opinions, ideas, and facts that support our beliefs.

In the end, our hypotheses are “almost never based on objective truth.” How could it be otherwise? But of course, the point is to know the limitations of the tools we’re working with and hope that awareness allows us to make better decisions by using better tools.

In Leo Tolstoy’s nonfiction magnum opus *The Kingdom of God Is Within You*, he writes:

“The most difficult subjects can be explained to the most slow-witted man if he has not formed any idea of them already; but the simplest thing cannot be made clear to the most intelligent man if he is firmly persuaded that he knows already, without a shadow of doubt, what is laid before him.”

If you can’t question assumptions at your company, you probably can’t question anything.

Assumption 4: Numbers Are the Only Truth

“Not everything that can be counted counts, and not everything that counts can be counted.” — Albert Einstein

The heart of default problem solving is quantitative analysis.

It has become so dominant that companies tend to forget that the world consists not only of quantities but also of qualities. Roger Martin, the dean of Rothman School of Management, argues that companies will simply lack ability to find the full potential of growth opportunities if they only focus on quantitative models: "The greatest weakness of the quantitative approach is that it decontextualizes human behavior, removing an event from its real-world setting and ignoring the effects of variables not included in the model." Default thinking catalogs the world into properties: how big is the market, how many people will buy our products, how many people know our brand, which category is growing fastest, which geography is the most profitable, which customers have the highest loyalty and what technologies have the highest adoption.

Yes, all of those have a numbers side, but they also have a qualitative side that might also shed light on things. If you know that a certain percent of your customers are happy with their interactions with your company, that's different than knowing what the experience of interacting with your company is like. Both of those things are needed to inform decisions. Numbers are great for covering your ass, so they tend to trump anything else. Numbers however, limit ideas and solutions to only one right answer.

For obvious reasons, the past does not include data on things that haven't happened or ideas that have not yet been imagined. As a result, data analysis of the future tends to underestimate or even ignore past events or conditions that can't be measured while overestimating those that can. Nowhere is this more visible than in business case studies. "In our view," the authors write, "the quantitative obsession leads to a sorely diminished approach to future planning. It tends to be conservative rather than creative because it implicitly favors what can be measured over what cannot."

Assumption 5: Language Needs to be Dehumanizing

Business and management science has become a world in itself, and the language of business has become increasingly technical, introverted, and coded. You don't fire people anymore; you "right-size the organization." You don't do the easiest things first; you "pick the low-hanging fruit." You don't look at where you sell your products; you "evaluate your channel mix." You don't promote people; you "leverage your human resources." You don't give people a bonus check; you "incentivize." You don't do stuff; you "execute." You "synergize, optimize, leverage, simplify, utilize, transform, enhance, and reengineer." You avoid "boiling the ocean, missing the paradigm shift, having tunnel vision, and increasing complexity." You make sure that "resources are allocated to leverage synergies across organizational boundaries and with a customer-centric mind-set that can secure a premium position while targeting white spots in the blue ocean to ensure that there is bang for the buck." It can become almost poetic.

Talk about jargon.

The German philosopher Jürgen Habermas has developed an extensive analysis of what happens when technical language outstrips the language of everyday life. He argues that the change from a normal, everyday language to a technical, specific language suggests a shift in power. When technical language conquers simple language of the every day, it is a sign that the system is gaining ground and everyday human reality, what he calls the lifeworld, is losing ground. He goes so far as to call this shift a colonization of the lifeworld; everyday life being colonized by a force of bureaucratization and rationalization that it cannot defend itself against. Such a shift leads to a far more systematic, rule-based, and technical idea of the world. It widens the gap between who we really are and the systems that we have become.

* * *

Of course, default thinking doesn't always work. You know you've stepped out of default thinking space when leaders say, "think outside the box." Problems arise when you try to solve the third type of problem (where there is a high level of uncertainty) with the same thinking you use to fix problems in one and two.

If you enjoyed this post, you'd love the book *The Moment of Clarity: Using the Human Sciences to Solve Your Toughest Business Problems*.

79. How Complex Systems Fail

A bit of a preface to this post. Please read the definition of Antifragile first. While the article below is interesting, the reader should read with a critical mind. Complexity 'solved' with increased complexity generally only creates a lot of hidden risks, slowness, or fragility.

A short treatise on the nature of failure; how failure is evaluated; how failure is attributed to proximate cause; and the resulting new understanding of patient safety by Richard I. Cook.

1. Complex systems are intrinsically hazardous systems

All of the interesting systems (e.g. transportation, healthcare, power generation) are inherently and unavoidably hazardous by their own nature. The frequency of hazard exposure can sometimes be changed but the processes involved in the system are themselves intrinsically and irreducibly hazardous. It is the presence of these hazards that drives the creation of defenses against hazard that characterize these systems.

2. Complex systems are heavily and successfully defended against failure

The high consequences of failure lead over time to the construction of multiple layers of defense against failure. These defenses include obvious technical components (e.g. backup systems, 'safety' features of equipment) and human components (e.g. training, knowledge) but also a variety of organizational, institutional, and regulatory defenses (e.g. policies and procedures, certification, work rules, team training). The effect of these measures is to provide a series of shields that normally divert operations away from accidents.

3. Catastrophe requires multiple failures – single point failures are not enough

The array of defenses works. System operations are generally successful. Overt catastrophic failure occurs when small, apparently innocuous failures join to create opportunity for a systemic accident. Each of these small failures is necessary to cause catastrophe but only the combination is sufficient to permit failure. Put another way, there are many more failure opportunities than overt system accidents. Most initial failure trajectories are blocked by designed system safety components. Trajectories that reach the operational level are mostly blocked, usually by practitioners.

4. Complex systems contain changing mixtures of failures latent within them

The complexity of these systems makes it impossible for them to run without multiple flaws being present. Because these are individually insufficient to cause failure they are regarded as minor factors during operations. Eradication of all latent failures is limited primarily by economic cost but also because it is difficult before the fact to see how such failures might contribute to an accident. The failures change constantly because of changing technology, work organization, and efforts to eradicate failures.

5. Complex systems run in degraded mode

A corollary to the preceding point is that complex systems run as broken systems. The system continues to function because it contains so many redundancies and because people can make it function, despite the presence of many flaws. After accident reviews nearly always note that the system has a history of prior 'proto-accidents' that nearly generated catastrophe. Arguments that these degraded conditions should have been recognized before the overt accident are usually predicated on naïve notions of system performance. System operations are dynamic, with components (organizational, human, technical) failing and being replaced continuously.

6. Catastrophe is always just around the corner

Complex systems possess potential for catastrophic failure. Human practitioners are nearly always in close physical and temporal proximity to these potential failures – disaster can occur at any time and in nearly any place. The potential for catastrophic outcome is a hallmark of complex systems. It is impossible to eliminate the potential for such catastrophic failure; the potential for such failure is always present by the system's own nature.

7. Post-accident attribution to a 'root cause' is fundamentally wrong

Because overt failure requires multiple faults, there is no isolated 'cause' of an accident. There are multiple contributors to accidents. Each of these is necessarily insufficient in itself to create an accident. Only jointly are these causes sufficient to create an accident. Indeed, it is the linking of these causes together that creates the circumstances required for the accident. Thus, no isolation of the 'root cause' of an accident is possible. The evaluations based on such reasoning as 'root cause' do not reflect a technical understanding of the nature of failure but rather the social, cultural need to blame specific, localized forces or events for outcomes.

8. Hindsight biases post-accident assessments of human performance

Knowledge of the outcome makes it seem that events leading to the outcome should have appeared more salient to practitioners at the time than was actually the case. This means that ex post facto accident analysis of human performance is inaccurate. The outcome knowledge poisons the ability of after-accident observers to recreate the view of practitioners before the accident of those same factors. It seems that practitioners "should have known" that the factors would "inevitably" lead to an accident. Hindsight bias remains the primary obstacle to accident investigation, especially when expert human performance is involved.

9. Human operators have dual roles: as producers & as defenders against failure

The system practitioners operate the system in order to produce its desired product and also work to forestall accidents. This dynamic quality of system operation, the balancing of demands for production against the possibility of incipient failure is unavoidable. Outsiders rarely acknowledge the duality of this role. In non-accident filled times, the production role is emphasized. After accidents, the defense against failure role is emphasized. At either time, the outsider's view misapprehends the operator's constant, simultaneous engagement with both roles.

10. All practitioner actions are gambles

After accidents, the overt failure often appears to have been inevitable and the practitioner's actions as blunders or deliberate willful disregard of certain impending failure. But all practitioner actions are actually gambles, that is, acts that take place in the face of uncertain outcomes. The degree of uncertainty may change from moment to moment. That practitioner actions are gambles appears clear after accidents; in general, post hoc analysis regards these gambles as poor ones. But the converse: that successful outcomes are also the result of gambles; is not widely appreciated.

11. Actions at the sharp end resolve all ambiguity

Organizations are ambiguous, often intentionally, about the relationship between production targets, efficient use of resources, economy and costs of operations, and acceptable risks of low and high consequence accidents. All ambiguity is resolved by actions of practitioners at the sharp end of the system. After an accident, practitioner actions may be regarded as 'errors' or 'violations' but these evaluations are heavily biased by hindsight and ignore the other driving forces, especially production pressure.

12. Human practitioners are the adaptable element of complex systems

Practitioners and first line management actively adapt the system to maximize production and minimize accidents. These adaptations often occur on a moment by moment basis. Some of these adaptations include: (1) Restructuring the system in order to reduce exposure of vulnerable parts to failure. (2) Concentrating critical resources in areas of expected high demand. (3) Providing pathways for retreat or recovery from expected and unexpected faults. (4) Establishing means for early detection of changed system performance in order to allow graceful cutbacks in production or other means of increasing resiliency.

13. Human expertise in complex systems is constantly changing

Complex systems require substantial human expertise in their operation and management. This expertise changes in character as technology changes but it also changes because of the need to replace experts who leave. In every case, training and refinement of skill and expertise is one part of the function of the system itself. At any moment, therefore, a given complex system will contain practitioners and trainees with varying degrees of expertise. Critical issues related to expertise arise from (1) the need to use scarce expertise as a resource for the most difficult or demanding production needs and (2) the need to develop expertise for future use.

14. Change introduces new forms of failure

The low rate of overt accidents in reliable systems may encourage changes, especially the use of new technology, to decrease the number of low consequence but high frequency failures. These changes maybe actually create opportunities for new, low frequency but high consequence failures. When new technologies are used to eliminate well understood system failures or to gain high precision performance they often introduce new pathways to large scale, catastrophic failures. Not uncommonly, these new, rare catastrophes have even greater impact than those eliminated by the new technology. These new forms of failure are difficult to see before the fact; attention is paid mostly to the putative beneficial characteristics of the changes. Because these new, high consequence accidents occur at a low rate, multiple system changes may occur before an accident, making it hard to see the contribution of technology to the failure.

15. Views of 'cause' limit the effectiveness of defenses against future events

Post-accident remedies for "human error" are usually predicated on obstructing activities that can "cause" accidents. These end-of-the-chain measures do little to reduce the likelihood of further accidents. In fact that likelihood of an identical accident is already extraordinarily low because the pattern of latent failures changes constantly. Instead of increasing safety, post-accident remedies usually increase the coupling and complexity of the system. This increases the potential number of latent failures and also makes the detection and blocking of accident trajectories more difficult.

16. Safety is a characteristic of systems and not of their components

Safety is an emergent property of systems; it does not reside in a person, device or department of an organization or system. Safety cannot be purchased or manufactured; it is not a feature that is separate from the other components of the system. This means that safety cannot be manipulated like a feedstock or raw material. The state of safety in any system is always dynamic; continuous systemic change insures that hazard and its management are constantly changing.

17. People continuously create safety

Failure free operations are the result of activities of people who work to keep the system within the boundaries of tolerable performance. These activities are, for the most part, part of normal operations and superficially straightforward. But because system operations are never trouble free, human practitioner adaptations to changing conditions actually create safety from moment to moment. These adaptations often amount to just the selection of a well-rehearsed routine from a store of available responses; sometimes, however, the adaptations are novel combinations or de novo creations of new approaches.

18. Failure free operations require experience with failure

Recognizing hazard and successfully manipulating system operations to remain inside the tolerable performance boundaries requires intimate contact with failure. More robust system performance is likely to arise in systems where operators can discern the "edge of the envelope". This is where system performance begins to deteriorate, becomes difficult to predict, or cannot be readily recovered. In intrinsically hazardous systems, operators are expected to encounter and appreciate hazards in ways that lead to overall performance that is desirable. Improved safety depends on providing operators with calibrated views of

the hazards. It also depends on providing calibration about how their actions move system performance towards or away from the edge of the envelope.

Here is a video of Richard talking about how complex systems don't fail.

80. Ruth Chang: How to Make Hard Choices

Ruth Chang is a philosopher at Rutgers University with an interesting background. After graduating with a J.D. from Harvard Law School and dipping her toe into the legal world, she went off to Oxford University to study philosophy. Her work focuses on how we make the decisions that shape our lives.

In her recent [TED talk](#) (video below), she talks about how we make hard choices and in the process offers a framework for making decisions consistent with who we truly are.

“Far from being sources of agony and dread, hard choices are precious opportunities for us to celebrate what is special about the human condition, that the reasons that govern our choices as correct or incorrect sometimes run out, and it is here, in the space of hard choices, that we have the power to create reasons for ourselves to become the distinctive people that we are. And that’s why hard choices are not a curse but a godsend.”

— Ruth Chang

How to Make Hard Choices

What makes a hard choice hard is the way alternatives relate.

In any easy choice, one alternative is better than the other. In a hard choice, one alternative is better in some ways, the other alternative is better in other ways, and neither is better than the other overall. You agonize over whether to stay in your current job in the city or uproot your life for more challenging work in the country because staying is better in some ways, moving is better in others, and neither is better than the other overall. We shouldn’t think that all hard choices are big. Let’s say you’re deciding what to have for breakfast. You could have high fiber bran cereal or a chocolate donut. Suppose what matters in the choice is tastiness and healthfulness. The cereal is better for you, the donut tastes way better, but neither is better than the other overall, a hard choice. Realizing that small choices can also be hard may make big hard choices seem less intractable. After all, we manage to figure out what to have for breakfast, so maybe we can figure out whether to stay in the city or uproot for the new job in the country.

In hard choices we tend to prefer the safest option.

... I can tell you that fear of the unknown, while a common motivational default in dealing with hard choices, rests on a misconception of them. It’s a mistake to think that in hard choices, one alternative really is better than the other, but we’re too stupid to know which, and since we don’t know which, we might as well take the least risky option. Even taking two alternatives side by side with full information, a choice can still be hard. Hard choices are hard not because of us or our ignorance; they’re hard because there is no best option. Now, if there’s no best option, if the scales don’t tip in favor of one alternative over another, then surely the alternatives must be equally good, so maybe the right thing to say in hard choices is that they’re between equally good options. That can’t be right. If alternatives are equally good, you should just flip a coin between them, and it seems a mistake to think, here’s how you should decide between careers, places to live, people to marry: Flip a coin. There’s another reason for thinking that hard choices aren’t choices between equally good options.

Our search for physics like exactitude and our desire to quantify everything into scientific thinking combine to lead us astray.

We unwittingly assume that values like justice, beauty, kindness, are akin to scientific quantities, like length, mass and weight. Take any comparative question not involving value, such as which of two suitcases is heavier? There are only three possibilities. The weight of one is greater, lesser or equal to the weight of the other. Properties like weight can be represented by real numbers — one, two, three and so on — and there are only three possible comparisons between any two real numbers. One number is greater, lesser, or equal to the other. Not so with values. As post-Enlightenment creatures, we tend to

assume that scientific thinking holds the key to everything of importance in our world, but the world of value is different from the world of science. The stuff of the one world can be quantified by real numbers. The stuff of the other world can't.

Another way to see things is that they are in the same ball-park. This is what happens in hard choices, the alternatives are "on a par."

When alternatives are on a par, it may matter very much which you choose, but one alternative isn't better than the other. Rather, the alternatives are in the same neighborhood of value, in the same league of value, while at the same time being very different in kind of value. That's why the choice is hard.

We create reasons.

Understanding hard choices in this way uncovers something about ourselves we didn't know. Each of us has the power to create reasons. Imagine a world in which every choice you face is an easy choice, that is, there's always a best alternative. If there's a best alternative, then that's the one you should choose, because part of being rational is doing the better thing rather than the worse thing, choosing what you have most reason to choose. ... A world full of only easy choices would enslave us to reasons. ... (However) when alternatives are on a par, the reasons given to us, the ones that determine whether we're making a mistake, are silent as to what to do. It's here, in the space of hard choices, that we get to exercise our normative power, the power to create reasons for yourself ... When we choose between options that are on a par, we can do something really rather remarkable. We can put our very selves behind an option. ... This response in hard choices is a rational response, but it's not dictated by reasons given to us. Rather, it's supported by reasons created by us. When we create reasons for ourselves to become this kind of person rather than that, we wholeheartedly become the people that we are. You might say that we become the authors of our own lives.

When you face hard choices you need to look inside yourself.

... Instead of looking for reasons out there, we should be looking for reasons in here: Who am I to be? You might decide to be a pink sock-wearing, cereal-loving, country-living banker, and I might decide to be a black sock-wearing, urban, donut-loving artist. What we do in hard choices is very much up to each of us.

If you don't exercise your normative powers you become a drifter.

Drifters allow the world to write the story of their lives. They let mechanisms of reward and punishment — pats on the head, fear, the easiness of an option — to determine what they do. So the lesson of hard choices reflect on what you can put your agency behind, on what you can be for, and through hard choices, become that person.

Hard choices are part of what makes us human.

Far from being sources of agony and dread, hard choices are precious opportunities for us to celebrate what is special about the human condition, that the reasons that govern our choices as correct or incorrect sometimes run out, and it is here, in the space of hard choices, that we have the power to create reasons for ourselves to become the distinctive people that we are. And that's why hard choices are not a curse but a godsend.

81. Kyle Bass: How Freediving Enables Better Decision Making

Below find an excerpt taken from an interview between Raoul Pal and Kyle Bass (a hedge fund manager based out of Texas.)

What resonates with me here is the need to find a way out of a world where we are pulled in a thousand different directions and find an internal quiet. In turn these quiet and intimate moments with ourselves enable us to excel.

Pal was asking about how Bass keeps balance in his life.

Kyle Bass: I've searched for that my whole life. I found it about six years ago. My favorite thing in the world is to do freediving and spearfishing. I know you live on an island. I could do that if I wasn't running this firm, meaning as a lifestyle choice. I have a little Hemingway in me.

Raoul Pal: What is it about spearfishing and freediving that you like? I don't spearfish. Freediving, I've had lessons in, and it's a fascinating thing because it's very internal.

Kyle: It's internal. It's a beautiful thing. It's like when you think about the greatest battles in the world, they've always been civil wars, just like I think the greatest battles you and I fight are in our head. It's between ourselves. The biggest battles that most people fight are with themselves.

When I was in college, I helped pay for college through ... I had a diving and an academic scholarship. I was, primarily, a springboard diver. That was, I would say, 80 percent mental, 20 percent physical, even though it looks all physical. It's you versus yourself. It's you convincing yourself that you can do this, and do it as well or better than anyone else. Freediving, very similar. It's you knowing yourself. It's you teaching yourself how to regulate your heart rate. It's how to control your emotions. It's made me better at controlling my emotions in the office.

Raoul: It's kind of where I was going to get to this.

Kyle: The beautiful part of freediving for me and spearfishing is the day-to-day "grind" that we go through. My phone rings 24/7. I take that back. I turn my phone off at night, so there's only a select few that can get through at night.

But during the day, I'm pulled in a thousand different directions. Regardless of how much I try to control my path through the day, things pop up. You have people everywhere pulling you 50 different ways.

The moment I go underwater in the ocean, it's Zen-like for me. My phone can't ring. No one can bother me. I'm typically there with people that I want to be there with, my team. I always dive with a team. Then it's me versus myself. It literally is Zen-like, and I've gotten so much better at being calm that I go 8-10 hours a day.

Raoul: Wow. Because a lot of people do the similar thing with yoga, and actually, yoga and freediving have a lot in common.

Kyle: Do they?

Raoul: Yeah. Lots of the great freedivers now learn yoga to understand how to control their body and control their minds.

Kyle: I have a problem with yoga. My mind drifts. When I'm freediving, I'm focused. I'm focused on the potential threats, because I primarily do it all in the Bahamas, so we see sharks every day. I'm not that afraid of sharks. I respect them.

The difference, for me, between yoga and freediving is in yoga you're sitting there, and you're in a solitary moment, and you're trying to focus on things mentally. But — I don't know, I need the freediving aspect of it to be really centered. ... That's how I get centered.

Raoul: Yeah, you have a physical focus then, as well.

Kyle: Yeah. I'm always searching for the next great hogfish, or grouper, or lobster to eat that night. We eat what we shoot. It's a beautiful, beautiful cycle that I go through, and I can do it for weeks on end.

Raoul: When did you take up freediving, and how did it change you in terms of how you work?

Kyle: It didn't, initially. It was just something I'd always wanted to do. I found a young man on an island in the Bahamas. I asked around and said, "Who's the best spearfisherman on the island?" Everybody said, "It's Dave. It's Dave. It's Dave."

This 17-year-old kid who had been bitten by sharks on his hand. He had been cut up on his foot by a propeller, and he's just a great kid. Over the years, he's become my boat captain. He's now, I guess, 23 years old. We've been partners now for six years. Every moment, every chance I get for vacation, that's where I go.

Raoul: As I said, you've actually noticed that whole process of learning that spill into your work, and it makes you calmer in how think about things?

Kyle: Yeah. You have to stay focused. If you trade on emotion, you lose every time. Every time. If you can divorce yourself of that, especially those real extreme and extremist, those emotions you feel, you have to go the other way. You have to.

82. The Inside View and Making Better Decisions

When we don't think about the process we use to make decisions, they tend to get worse over time as we fail to learn from experience. Often, we make decisions based on the information that is easiest to access. Let's learn how to take the outside view and make better decisions.

In his book Think Twice: Harnessing the Power of Counterintuition, Michael Mauboussin discusses how we can “fall victim to simplified mental routines that prevent us from coping with the complex realities inherent in important judgment calls.” One of those routines is the inside view, which we're going to talk about in this article but first let's get a bit of context.

No one wakes up thinking, “I am going to make bad decisions today.” Yet we all make them. What is particularly surprising is some of the biggest mistakes are made by people who are, by objective standards, very intelligent. Smart people make big, dumb, and consequential mistakes.

[...]

Mental flexibility, introspection, and the ability to properly calibrate evidence are at the core of rational thinking and are largely absent on IQ tests. Smart people make poor decisions because they have the same factory settings on their mental software as the rest of us, and that software isn't designed to cope with many of today's problems.

We don't spend enough time thinking and learning from the process. Generally, we're pretty ambivalent about the process by which we make decisions.

... typical decision makers allocate only 25 percent of their time to thinking about the problem properly and learning from experience. Most spend their time gathering information, which feels like progress and appears diligent to superiors. But information without context is falsely empowering.

That reminds me of what Daniel Kahneman wrote in Thinking, Fast and Slow:

A remarkable aspect of your mental life is that you are rarely stumped ... The normal state of your mind is that you have intuitive feelings and opinions about almost everything that comes your way. You like or dislike people long before you know much about them; you trust or distrust strangers without knowing why; you feel that an enterprise is bound to succeed without analyzing it.

Context comes from broad understanding — looking at the problem from the outside in and not the inside out. When we make a decision, we're not really gathering and contextualizing information as much as trying to satisfy our existing intuition; The very thing a good decision process should help root out. Think about it this way, every time you make a decision, you're saying you understand something. Most of us stop there. But understanding is not enough; you need to test that your understanding is correct, which comes through feedback and reflection. Then you need to update your understanding. This is the learning loop.

So why are we so quick to assume we understand?

Ego Induced Blindness

We tend to favor the inside view over the outside view.

An inside view considers a problem by focusing on the specific task and by using information that is close at hand, and makes predictions based on that narrow and unique set of inputs. These inputs may include anecdotal evidence and fallacious perceptions.

This is the approach that most people use in building models of the future and is indeed common for all forms of planning.

[...]

The outside view asks if there are similar situations that can provide a statistical basis for making a decision. Rather than seeing a problem as unique, the outside view wants to know if others have faced comparable problems and, if so, what happened. The outside

view is an unnatural way to think, precisely because it forces people to set aside all the cherished information they have gathered.

When the inside view is more positive than the outside view, you're saying (knowingly or, more likely, unknowingly) that this time is different. Our brains are all too happy to help us construct this argument.

Mauboussin argues that we embrace the inside view for a few primary reasons. First, we're optimistic by nature. Second, is the "illusion of optimism" (we see our future as brighter than that of others). Finally, it is the illusion of control (we think that chance events are subject to our control).

One interesting point is that while we're bad at looking at the outside view when it comes to ourselves, we're better at it when it comes to other people.

In fact, the planning fallacy embodies a broader principle. When people are forced to look at similar situations and see the frequency of success, they tend to predict more accurately. If you want to know how something is going to turn out for you, look at how it turned out for others in the same situation. Daniel Gilbert, a psychologist at Harvard University, ponders why people don't rely more on the outside view, "Given the impressive power of this simple technique, we should expect people to go out of their way to use it. But they don't." The reason is most people think of themselves as different, and better, than those around them.

So it's mostly ego. I'm better than the people tackling this problem before me. We see the differences between situations and use those as rationalizations as to why things are different this time.

Consider this:

We incorrectly think that differences are more valuable than similarities.

After all, anyone can see what's the same but it takes true insight to see what's different, right? We're all so busy trying to find differences that we forget to pay attention to what is the same.

Incorporating the Outside View

In Think Twice, Mauboussin distills the work of Kahneman and Tversky into four steps and adds some commentary.

1. Select a Reference Class

Find a group of situations, or a reference class, that is broad enough to be statistically significant but narrow enough to be useful in analyzing the decision that you face. The task is generally as much art as science, and is certainly trickier for problems that few people have dealt with before. But for decisions that are common—even if they are not common for you—identifying a reference class is straightforward. Mind the details. Take the example of mergers and acquisitions. We know that the shareholders of acquiring companies lose money in most mergers and acquisitions. But a closer look at the data reveals that the market responds more favorably to cash deals and those done at small premiums than to deals financed with stock at large premiums. So companies can improve their chances of making money from an acquisition by knowing what deals tend to succeed.

2. Assess the distribution of outcomes.

Once you have a reference class, take a close look at the rate of success and failure. ... Study the distribution and note the average outcome, the most common outcome, and extreme successes or failures.

[...]

Two other issues are worth mentioning. The statistical rate of success and failure must be reasonably stable over time for a reference class to be valid. If the properties of the system change, drawing inference from past data can be misleading. This is an important issue in personal finance, where advisers make asset allocation recommendations for their clients

based on historical statistics. Because the statistical properties of markets shift over time, an investor can end up with the wrong mix of assets.

Also keep an eye out for systems where small perturbations can lead to large-scale change. Since cause and effect are difficult to pin down in these systems, drawing on past experiences is more difficult. Businesses driven by hit products, like movies or books, are good examples. Producers and publishers have a notoriously difficult time anticipating results, because success and failure is based largely on social influence, an inherently unpredictable phenomenon.

3. Make a prediction.

With the data from your reference class in hand, including an awareness of the distribution of outcomes, you are in a position to make a forecast. The idea is to estimate your chances of success and failure. For all the reasons that I've discussed, the chances are good that your prediction will be too optimistic.

Sometimes when you find the right reference class, you see the success rate is not very high. So to improve your chance of success, you have to do something different than everyone else.

4. Assess the reliability of your prediction and fine-tune.

How good we are at making decisions depends a great deal on what we are trying to predict. Weather forecasters, for instance, do a pretty good job of predicting what the temperature will be tomorrow. Book publishers, on the other hand, are poor at picking winners, with the exception of those books from a handful of best-selling authors. The worse the record of successful prediction is, the more you should adjust your prediction toward the mean (or other relevant statistical measure). When cause and effect is clear, you can have more confidence in your forecast.

The main lesson we can take from this is that we tend to focus on what's different whereas the best decisions often focus on just the opposite: what's the same. While this situation seems a little different, it's almost always the same.

As Charlie Munger has said: "if you notice, the plots are very similar. The same plot comes back time after time."

Particulars may vary but, unless those particulars are the variables that govern the outcome of the situation, the pattern remains. If we're going to focus on what's different rather than what's the same, you'd best be sure the variables you're clinging to matter.

Article Summary

- *"You can reduce the number of mistakes you make by thinking about problems more clearly."*
- Most decision-makers don't spend enough time on the process of making decisions or learning from their mistakes.
- Feedback and reflection are necessary components to learn from experience.
- When you think this time is different, you're saying you will succeed where others have failed.
- To better incorporate a broader view, you can select a reference class, assess the distribution of outcomes, make a prediction, and calibrate your accuracy.
- We tend to focus on what's different, whereas many of the best decisions focus on what's the same.

83. The Mind's Search Algorithm: Sorting Mental Models

Mental models are tools for the mind.

In his talk: Academic Economics: Strengths and Weaknesses, after Considering Interdisciplinary Needs, at the University of California at Santa Barbara, in 2003, Charlie Munger honed in on why we like to specialize.

The big general objection to economics was the one early described by Alfred North Whitehead when he spoke of the fatal unconnectedness of academic disciplines, wherein each professor didn't even know of the models of the other disciplines, much less try to synthesize those disciplines with his own ... The nature of this failure is that it creates what I always call 'man with a hammer' syndrome. To a man with only a hammer, every problem looks pretty much like a nail. And that works marvellously to gum up all professions, and all departments of academia, and indeed most practical life. So, what do we do, Charlie? The only antidote for being an absolute klutz due to the presence of a man with a hammer syndrome is to have a full kit of tools. You don't have just a hammer. You've got all the tools.

The more models you have from outside your discipline and the more you iterate through them when faced with a challenge in a checklist sort of fashion, the better you'll be able to solve problems.

Models are additive. Like LEGO. The more you have the more things you can build, the more connections you can make between them and the more likely you are to be able to determine the relevant variables that govern the situation.

And when you learn these models you need to ask yourself under what conditions will this tool fail? That way you're not only looking for situations where the tool is useful but also situations where something interesting is happening that might warrant further attention.

The Mind's Search Engine

In Diaminds: Decoding the Mental Habits of Successful Thinkers, Roger Martin looks at our mental search engine.

Now for the final step in the design of the mentally choiceful stance: the search engine, as in 'How did I solve these problems?' 'Obviously,' you will answer yourself, 'I was using a simple search engine in my mind to go through checklist style, and I was using some rough algorithms that work pretty well in many complex systems.' What does a search engine do? It searches. And how do you organize an efficient search? Well, algorithm designers tell us you have to have an efficient organization of the contents of whatever it is you are searching. And a tree structure allows you to search more efficiently than most alternative structures.

How a tree structure helps simplify search: A detection algorithm for 'Fox.'
 So what's Munger's search algorithm?
 (from an interview with Munger via Diamonds: Decoding the Mental Habits of Successful Thinkers.)

Extreme success is likely to be caused by some combination of the following factors: a) Extreme maximization or minimization of one or two variables. Example[:] Costco, or, [Berkshire Hathaway's] furniture and appliance store. b) Adding success factors so that a bigger combination drives success, often in nonlinear fashion, as one is reminded of the concept of breakpoint or the concept of critical mass in physics. You get more mass, and you get a lollapalooza result. And of course I've been searching for lollapalooza results all my life, so I'm very interested in models that explain their occurrence. [Remember the Black Swan?] c) an extreme of good performance over many factors. Examples: Toyota or Les Schwab. d) Catching and riding some big wave.

Charlie Munger's lollapalooza detection algorithm represented as a tree search.
 (via Diamonds: Decoding the Mental Habits of Successful Thinkers)

A good search algorithm allows you to make your mental choices clear. It makes it easier for you to be mentally choiceful and to understand the reasons why you're making these mental choices.

Now, what should go on the branches of your tree of mental models? Well, how about basic mental models from a whole bunch of different disciplines? Such as: physics (non-linearity, criticality), economics (what Munger calls the 'super-power' of incentives), the multiplicative effects of several interacting causes (biophysics), and collective phenomena – or 'catching the wave' (plasma physics). How's that for a science that rocks, by placing at the disposal of the mind a large library of forms created by thinkers across hundreds of years and marshalling them for the purpose of detecting, building, and profiting from Black Swans?

The 'tree trick' has one more advantage – a big one: it lets you quickly visualize interactions among the various models and identify cumulative effects. Go northwest in your search, starting from the '0' node, and the interactions double with every step. Go southwest, on the other hand, and the interactions decrease in number at the same rate. Seen in this rather sketchy way, Black Swan hunting is no longer as daunting a sport as it might seem at first sight.

84. 13 Practical Ideas That Have Helped Me Make Better Decisions

This article is a collaboration between Mark Steed and myself. He did most of the work. Mark was a participant at the last Re:Think Decision Making event as well as a member of the Good Judgment Project. I asked him to put together something on making better predictions. This is the result.

We all face decisions. Sometimes we think hard about a specific decision, other times, we make decisions without thinking. If you've studied the genre you've probably read Taleb, Tversky, Kahneman, Gladwell, Ariely, Munger, Tetlock, Mauboussin and/or Thaler. These pioneers write a lot about "rationality" and "biases".

Rationality dictates the selection of the best choice among however many options. Biases of a cognitive or emotional nature creep in and are capable of preventing the identification of the "rational" choice. These biases can exist in our DNA or can be formed through life experiences. The mentioned authors consider biases extensively, and, lucky for us, their writings are eye-opening and entertaining.

Rather than rehash what brighter minds have discussed, I'll focus on practical ideas that have helped me make better decisions. I think of this as a list of "lessons learned (so far)" from my work in asset management and as a forecaster for the Good Judgment Project. I've held back on submitting this given the breadth and depth of the FS readers, but, rather than expect perfection, I wanted to put something on the table because I suspect many of you have useful ideas that will help move the conversation forward.

1. This is a messy business. Studying decision science can easily motivate self-loathing. There are over one-hundred cognitive biases that might prevent us from making calculated and "rational" decisions. What, you can't create a decision tree with 124 decision nodes, complete with assorted probabilities in split seconds? I asked around, and it turns out, not many people can. Since there is no way to eliminate all the potential cognitive biases and I don't possess the mental faculties of Dr. Spock or C-3PO, I might as well live with the fact that some decisions will be more elegant than others.

2. We live and work in dynamic environments. Dynamic environments adapt. The opposite of dynamic environments are static environments. Financial markets, geopolitical events, team sports, etc. are examples of dynamic "environments" because relationships between agents evolve and problems are often unpredictable. Changes from one period are conditional on what happened the previous period. Casinos are more representative of static environments. Not casinos necessarily, but the games inside. If you play Roulette, your odds of winning are always the same and it doesn't matter what happened the previous turn.

3. Good explanatory models are not necessarily good predictive models. Dynamic environments have a habit of desecrating rigid models. While blindly following an elegant model may be ill-advised, strong explanatory models are excellent guideposts when paired with sound judgment and intuition. Just as I'm not comfortable with the automatic pilot flying a plane without a human in the cockpit, I'm also not comfortable with a human flying a plane without the help of technology. It has been said before, people make models better and models make people better.

4. Instinct is not always irrational. The rule of thumb, otherwise known as heuristics, provide better results than more complicated analytical techniques. Gerd Gigerenzer, is the thought leader and his book Risk Savvy: How to Make Good Decisions is worth reading. Most literature despises heuristics, but he asserts intuition proves superior because optimization is sometimes mathematically impossible or exposed to sampling error. He often uses the example of Harry Markowitz, who won a Nobel Prize in Economics in 1990 for his work on Modern Portfolio Theory. Markowitz discovered a method for determining the "optimal" mix of assets. However, Markowitz himself did not

follow his Nobel prize-winning mean-variance theory but instead used a $1/N$ heuristic by spreading his dollars equally across N number of investments. He concluded that his $1/N$ strategy would perform better than a mean-optimization application unless the mean-optimization model had 500 years to compete. Our intuition is more likely to be accurate if it is preceded by rigorous analysis and introspection. And simple rules are more effective at communicating winning strategies in complex environments. When coaching a child's soccer team, it is far easier teaching a few basic principles, than articulating the nuances of every possible situation.

5. Decisions are not evaluated in ways that help us reduce mistakes in the future. Our tendency is to only critique decisions where the desired outcome was not achieved while uncritically accepting positive outcomes even if luck, or another factor, produced the desired result. At the end of the day I understand all we care about are results, but good processes are more indicative of future success than good results.

6. Success is ill-defined. In some cases this is relatively straightforward. If the outcome is binary, either it did, or did not happen, success is easy to identify. But this is more difficult in situations where the outcome can take a range of potential values, or when individuals differ on what the values should be.

7. We should care a lot more about calibration. Confidence, not just a decision, should be recorded (and to be clear, decisions should be recorded). Next time you have a major decision, ask yourself how confident you are that the desired outcome will be achieved. Are you 50% confident? 90%? Write it down. This helps with calibration. For all decisions in which you are 50% confident, half should be successes. And you should be right nine out of ten times for all decisions in which you are 90% confident. If you are 100% confident, you should never be wrong. If you don't know anything about a specific subject then you should be no more confident than a coin flip. It's amazing how we will assign high confidence to an event we know nothing about. Turns out this idea is pretty helpful. Let's say someone brings an idea to you and you know nothing about it. Your default should be 50/50; you might as well flip a coin. Then you just need to worry about the costs/payouts.

8. Probabilities are one thing, payouts are another. You might feel 50/50 about your chances but you need to know your payouts if you are right. This is where the expected value comes in handy. It's the probability of being right multiplied by the payout if you are right, plus the probability of being wrong multiplied by the cost. $E = .50(x) + .50(y)$. Say someone on your team has an idea for a project and you decided there is a 50% chance that it succeeds and, if it does, you double your money, if it doesn't, you lose what you invested. If the project required \$10mm, then the expected outcome is calculated as $.50*20 + .50*0 = 10$, or \$10mm. If you repeat this process a number of times, approving only projects with a 2:1 payout and 50% probability of success you would likely end up with the same amount you started with. Binary outcomes that have a 50/50 probability should have a double-or-nothing payout. This is even more helpful given #7 above. If you were tracking this employee's calibration you would have a sense as to whether their forecasts are accurate. As a team member or manager, you would want to know if a specific employee is 90% confident all the time but only 50% accurate. More importantly, you would want to know if a certain team member is usually right when they express 90% or 100% confidence. Use a Brier Score to track colleagues but provide an environment to encourage discussion and openness.

9. We really are overconfident. Starting from the assumption that we are probably only 50% accurate is not a bad idea. Phil Tetlock, a professor at UPenn, Team Leader for the Good Judgment Project and author of Expert Political Judgment: How Good Is It? How Can We Know?, suggested political pundits are about 53% accurate regarding political forecasts while CXO Advisory tracks investment gurus and finds they are, in aggregate, about 48% accurate. These are experts making predictions about their core area of expertise. Consider the rate of divorce in the U.S., currently around 40%-50%, as

additional evidence that sometimes we don't know as much as we think. Experts are helpful in explaining a specific discipline but they are less helpful in dynamic environments. If you need something fixed, like a car, a clock or an appliance then experts can be very helpful. Same for tax and accounting advice. It's not because this stuff is simple, it's because the environment is static.

10. Improving estimations of probabilities and payouts is about polishing our 1) subject matter expertise and 2) cognitive processing abilities. Learning more about a given subject reduces uncertainty and allows us to move from the lazy 50/50 forecast. Say you travel to Arizona and get stung by a scorpion. Rather than assume a 50% probability of death you can do a quick internet search and learn no one has died from a scorpion bite in Arizona since the 1960s. Overly simplistic, but, you get the picture. Second, data needs to be interpreted in a cogent way. Let's say you work in asset management and one of your portfolio managers has made three investments that returned -5%, -12% and 22%. What can you say about the manager (other than two of the three investments lost money)? Does the information allow you to claim the portfolio manager is a bad manager? Does the information allow you to claim you can confidently predict his/her average rate of return? Unless you've had some statistics, it might not be entirely clear what clinical conclusions you can draw. What if you flipped a coin three times and came up with tails on two of them? That wouldn't seem so strange. Two-thirds is the same as 66%. If you tossed the coin one-hundred times and got 66 tails, that would be a little more interesting. The more observations, the higher our confidence should be. A 95% confidence interval for the portfolio manager's average return would be a range between -43% and 45%. Is that enough to take action?

11. Bayesian analysis is more useful than we think. Bayesian updating helps direct given false/true positives and false/true negatives. It's the probability of a hypothesis given some observed data. For example, what's the likelihood of X (this new hire will place in the top 10% of the firm) given Y (they graduated from an Ivy League school)? A certain percentage of employees are top-performing employees, some Ivy League grads will be top-performers (others not) and some non-Ivy League grads will be top-performers (others not). If I'm staring at a random employee trying to guess whether they are a top-performing employee all I have are the starting odds, and, if only the top 10% qualify, I know my chances are 1 in 10. But I can update my odds if supplied information regarding their education. Here's another example. What is the likelihood a project will be successful (X) given it missed one of the first two milestones (Y)? There are lots of helpful resources online if you want to learn more but think of it this way (hat tip to Kalid Azad at Better Explained); original odds x the evidence adjustment = your new odds. The actual equation is more complicated but that is the intuition behind it. Bayesian analysis has its naysayers. In the examples provided, the prior odds of success are known, or could easily be obtained, but this isn't always true. Most of the time subjective prior probabilities are required and this type of tomfoolery is generally discouraged. There are ways around that, but no time to explain it here.

12. A word about crowds. Is there a wisdom of crowds? Some say yes, others say no. My view is that crowds can be very useful if individual members of the crowd are able to vote independently or if the environment is such that there are few repercussions for voicing disagreement. Otherwise, I think signaling effects from seeing how others are "voting" is too much evolutionary force to overcome with sheer rational willpower. Our earliest ancestors ran when the rest of the tribe ran. Not doing so might have resulted in an untimely demise.

13. Analyze your own motives. Jonathan Haidt, author of The Righteous Mind: Why Good People Are Divided by Politics and Religion, is credited with teaching that logic isn't used to find truth, it's used to win arguments. Logic may not be the only source of truth (and I

have no basis for that claim). Keep this in mind as it has to do with the role of intuition in decision making.

Just a few closing thoughts.

We are pretty hard on ourselves. My process is to make the best decisions I can, realizing not all of them will be optimal. I have a method to track my decisions and to score how accurate I am. Sometimes I use heuristics, but I try to keep those to within my area of competency, as Munger says. I don't do lists of pros and cons because I feel like I'm just trying to convince myself, either way.

If I have to make a big decision, in an unfamiliar area, I try to learn as much as I can about the issue on my own and from experts, assess how much randomness could be present, formulate my thesis, look for contradictory information, try and build downside protection (risking as little as possible) and watch for signals that may indicate a likely outcome.

Many of my decisions have not worked out, but most of them have. As the world changes, so will my process, and I look forward to that.

85. The Wisdom of Crowds and The Expert Squeeze

As networks harness the wisdom of crowds, the ability of experts to add value in their predictions is steadily declining. This is the expert squeeze.

In Think Twice: Harnessing the Power of Counterintuition, Michael Mauboussin, the first guest on my podcast, The Knowledge Project, explains the expert squeeze and its implications for how we make decisions.

As networks harness the wisdom of crowds and computing power grows, the ability of experts to add value in their predictions is steadily declining. I call this the expert squeeze, and evidence for it is mounting. Despite this trend, we still pine for experts— individuals with special skill or know-how— believing that many forms of knowledge are technical and specialized. We openly defer to people in white lab coats or pinstripe suits, believing they hold the answers, and we harbor misgivings about computergenerated outcomes or the collective opinion of a bunch of tyros.

The expert squeeze means that people stuck in old habits of thinking are failing to use new means to gain insight into the problems they face. Knowing when to look beyond experts requires a totally fresh point of view, and one that does not come naturally. To be sure, the future for experts is not all bleak. Experts retain an advantage in some crucial areas. The challenge is to know when and how to use them.

Domain description	Rule based; limited range of outcomes	Rule based; wide range of outcomes	Probabilistic; limited range of outcomes	Probabilistic; wide range of outcomes
Expert performance	Worse than computers	Generally better than computers	Equal to or worse than collectives	Worse than collectives
Expert agreement	High	Moderate	Moderate/Low	Low
Examples	• Credit scoring • Simple medical diagnosis	• Chess • Go	• Admissions officers • Poker	• Stock market • Economy

The Value of Experts

So how can we manage this in our role as the decision-maker? The first step is to classify the problem.

(The figure above — The Value of Experts) helps to guide this process. The second column from the left covers problems that have rules-based solutions with limited possible outcomes. Here, someone can investigate the problem based on past patterns and write down rules to guide decisions. Experts do well with these tasks, but once the principles are clear and well defined, computers are cheaper and more reliable. Think of tasks such as credit scoring or simple forms of medical diagnosis. Experts agree about how to approach these problems because the solutions are transparent and for the most part tried and true. [...]

Now let's go to the opposite extreme, the column on the far right that deals with probabilistic fields with a wide range of outcomes. Here are no simple rules. You can only express possible outcomes in probabilities, and the range of outcomes is wide. Examples

include economic and political forecasts. The evidence shows that collectives outperform experts in solving these problems.

[...]

The middle two columns are the remaining province for experts. Experts do well with rules-based problems with a wide range of outcomes because they are better than computers at eliminating bad choices and making creative connections between bits of information.

Once you've classified the problem, you can turn to the best method for solving it.

... computers and collectives remain underutilized guides for decision making across a host of realms including medicine, business, and sports. That said, experts remain vital in three capacities. First, experts must create the very systems that replace them. ... Of course, the experts must stay on top of these systems, improving the market or equation as need be.

Next, we need experts for strategy. I mean strategy broadly, including not only day-to-day tactics but also the ability to troubleshoot by recognizing interconnections as well as the creative process of innovation, which involves combining ideas in novel ways. Decisions about how best to challenge a competitor, which rules to enforce, or how to recombine existing building blocks to create novel products or experiences are jobs for experts.

Finally, we need people to deal with people. A lot of decision making involves psychology as much as it does statistics. A leader must understand others, make good decisions, and encourage others to buy in to the decision.

So what are the practical tips you can do to make the expert squeeze work for you instead of against you? Here Mauboussin offers 3 tips.

1. Match the problem you face with the most appropriate solution.

What we know is that experts do a poor job in many settings, suggesting that you should try to supplement expert views with other approaches.

2. Seek diversity.

(Philip) Tetlock's work shows that while expert predictions are poor overall, some are better than others. What distinguishes predictive ability is not who the experts are or what they believe, but rather how they think. Borrowing from Archilochus— through Isaiah Berlin — Tetlock sorted experts into hedgehogs and foxes. Hedgehogs know one big thing and try to explain everything through that lens. Foxes tend to know a little about a lot of things and are not married to a single explanation for complex problems. Tetlock finds that foxes are better predictors than hedgehogs. Foxes arrive at their decisions by stitching "together diverse sources of information," lending credence to the importance of diversity. Naturally, hedgehogs are periodically right— and often spectacularly so— but do not predict as well as foxes over time. For many important decisions, diversity is the key at both the individual and collective levels.

3. Use technology when possible. Leverage technology to side-step the squeeze when possible.

Flooded with candidates and aware of the futility of most interviews, Google decided to create algorithms to identify attractive potential employees. First, the company asked seasoned employees to fill out a three-hundred-question survey, capturing details about their tenure, their behavior, and their personality. The company then compared the survey results to measures of employee performance, seeking connections. Among other findings, Google executives recognized that academic accomplishments did not always correlate with on-the-job performance. This novel approach enabled Google to sidestep problems with ineffective interviews and to start addressing the discrepancy.

Learning the difference between when experts help or hurt can go a long way toward avoiding stupidity. This starts with identifying the type of problem you're facing and then considering the various approaches to solve the problem with pros and cons.

86. Simple Rules: How to Thrive in a Complex World

"Decision rules—boundary, prioritizing, and stopping—provide clear guidelines for making better decisions across many situations and in the most challenging circumstances."

"Simple rules work because they do three things well.

First, they allow for flexibility in the pursuit of new opportunities, avoiding the rigidity of too many rules and the chaos of none at all. They are particularly effective when the situation is in flux, flexibility trumps consistency, and the benefits of seizing opportunities exceed the cost of making mistakes. Second, simple rules can produce decisions that match or outperform more sophisticated decision models across a wide variety of possible scenarios, and do so quickly, with limited data requirements, and when cause and effect are imperfectly understood. Their simplicity, in addition, increases the odds that people will remember them, act on them, and stick with them over time. Finally, collective action, like the honeybees' choice of nest, can emerge from simple rules even when individuals' mental capacity is limited and no one member understands the situation in its entirety."

Simple Rules: How to Thrive in a Complex World

The 4 common traits that define simple rules ...

1. "Simple rules consist of a handful of guidelines applied to a specific activity or decision..."
2. "Simple rules are tailored to the situations of the particular people who will use them, versus one-size-fits-all rules that apply to everyone."
3. "Simple rules are most effective when they apply to critical activities or decisions that represent bottlenecks to accomplishing an important goal."
4. "simple rules give concrete guidance without being overly prescriptive."

"A hammer is just the thing for nails, but useless when it comes to sawing a plank. The same is true of simple rules: to be effective, they must fit the task at hand. Simple rules work best when flexibility matters more than consistency."

"Simple rules are shortcut strategies that save time and effort by focusing our attention and simplifying the way we process information. The rules aren't universal—they're tailored to the particular situation and the person using them."

We use simple rules to guide decision making every day.

In fact, without them, we'd be paralyzed by the sheer mental brainpower required to sift through the complicated messiness of our world. You can think of them as heuristics. Like heuristics, most of the time they work yet some of the time they don't.

Simple Rules: How to Thrive in a Complex World, a book by Donald Sull and Kathleen Eisenhardt, explores the understated power that comes from using simple rules. As they define them, simple rules refer to "a handful of guidelines tailored to the user and the task at hand, which balance concrete guidance with the freedom to exercise judgment." These rules "provide a powerful weapon against the complexity that threatens to overwhelm individuals, organizations, and society as a whole. Complexity arises whenever a system—technical, social, or natural—has multiple interdependent parts."

They work, the authors argue, because they do three things well.

First, they confer the flexibility to pursue new opportunities while maintaining some consistency. Second, they can produce better decisions. When information is limited and time is short, simple rules make it fast and easy for people, organizations, and governments to make sound choices. They can even outperform complicated decision-

making approaches in some situations. Finally, simple rules allow the members of a community to synchronize their activities with one another on the fly.

Effective simple rules share four common traits ...

First, they are limited to a handful. Capping the number of rules makes them easy to remember and maintains a focus on what matters most. Second, simple rules are tailored to the person or organization using them. College athletes and middle-aged dieters may both rely on simple rules to decide what to eat, but their rules will be very different. Third, simple rules apply to a well-defined activity or decision, such as prioritizing injured soldiers for medical care. Rules that cover multiple activities or choices end up as vague platitudes, such as “Do your best” and “Focus on customers.” Finally, simple rules provide clear guidance while conferring the latitude to exercise discretion.

Simple Rules for a Complex World

People often attempt to address complex problems with complex solutions. For example, governments tend to manage complexity by trying to anticipate every possible scenario that might arise, and then promulgate regulations to cover every case.

Consider how central bankers responded to increased complexity in the global banking system. In 1988 bankers from around the world met in Basel, Switzerland, to agree on international banking regulations, and published a 30-page agreement (known as Basel I). Sixteen years later, the Basel II accord was an order of magnitude larger, at 347 pages, and Basel III was twice as long as its predecessor. When it comes to the sheer volume of regulations generated, the U.S. Congress makes the central bankers look like amateurs. The Glass-Steagall Act, a law passed during the Great Depression, which guided U.S. banking regulation for seven decades, totaled 37 pages. Its successor, Dodd-Frank, is expected to weigh in at over 30,000 pages when all supporting legislation is complete. Meeting complexity with complexity can create more confusion than it resolves. The policies governing U.S. income taxes totaled 3.8 million words as of 2010. Imagine a book that is seven times as long as War and Peace, but without any characters, plot points, or insight into the human condition. That book is the U.S. tax code.

[...]

Applying complicated solutions to complex problems is an understandable approach, but flawed. The parts of a complex system can interact with one another in many different ways, which quickly overwhelms our ability to envision all possible outcomes.

[...]

Complicated solutions can overwhelm people, thereby increasing the odds that they will stop following the rules. A study of personal income tax compliance in forty-five countries found that the complexity of the tax code was the single best predictor of whether citizens would dodge or pay their taxes. The complexity of the regulations mattered more than the highest marginal tax rate, average levels of education or income, how fair the tax system was perceived to be, and the level of government scrutiny of tax returns.

Simple Rules Focus on the Critical Variables

Simple rules do not trump complicated ones all the time but they work more often than we think. Gerd Gigerenzer is a key contributor in this space. He thinks that simple rules can allow for better decision making.

Why can simpler models outperform more complex ones? When underlying cause-and-effect relationships are poorly understood, decision makers often look for patterns in historical data under the assumption that past events are a good indicator of future trends. The obvious problem with this approach is that the future may be genuinely different from the past. But a second problem is subtler. Historical data includes not only useful signal, but also noise—happenstance correlations between variables that do not reveal an enduring cause-and-effect relationship. Fitting a model too closely to historical data hardwires error into the model, which is known as overfitting. The result is a precise prediction of the past that may tell us little about what the future holds.

Simple rules focus on the critical variables that govern a situation and help you ignore the peripheral ones. Of course, in order to identify the key variables, you need to be operating in your circle of competence. When we pay too much attention to irrelevant or otherwise unimportant information, we fail to grasp the power of the most important ones and give them the weighting they deserve. Simple rules also make it more likely people will act on them. This is something Napoleon intuitively understood.

When instructing his troops, Napoleon realized that complicated instructions were difficult to understand, explain, and execute. So, rather than complicated strategies he passed along simple ones, such as: Attack.

Making Better Decisions

The book mentions three types of rules that “improve decision making by structuring choices and centering on what to do (and what not to do): boundary, prioritizing, and stopping rules.

Boundary Rules cover what to do ...

Boundary rules guide the choice of what to do (and not do) without requiring a lot of time, analysis, or information. Boundary rules work well for categorical choices, like a judge’s yes-or-no decision on a defendant’s bail, and decisions requiring many potential opportunities to be screened quickly. These rules also come in handy when time, convenience, and cost matter.

Prioritizing rules rank options to help decide which of multiple paths to pursue.

Prioritizing rules can help you rank a group of alternatives competing for scarce money, time, or attention. ... They are especially powerful when applied to a bottleneck, an activity or decision that keeps individuals or organizations from reaching their objectives.

Bottlenecks represent pinch-points in companies, where the number of opportunities swamps available resources, and prioritizing rules can ensure that these resources are deployed where they can have the greatest impact. In business settings, prioritizing rules can be used to assign engineers to new-product-development projects, focus sales representatives on the most promising customers, and allocate advertising expenditure across multiple products, to name only a few possibilities.

Stopping rules help you learn when to reverse a decision. Nobel Prize-winning economist Herbert Simon argued that we lack the information, time, and mental engine to determine the single best path when faced with a slew of options. Instead, we rely on a heuristic to help us stop searching when we find something that’s good enough. Simon called this satisficing. If you think that’s hard, it’s even hard to stop doing something we’re already doing. Yet when it comes to our key investments of time, money, and energy we have to know when to pull the plug.

Sometimes we pursue goals at all costs and ignore our self-imposed stopping rule.

This goal induced blindness can be deadly.

A cross-continental team of researchers matched 145 Chicagoans with demographically similar Parisians. Both the Chicagoans and Parisians used stopping rules to decide when to finish eating, but the rules themselves were very different. The Parisians employed rules like “Stop eating when I start feeling full,” linking their decision to internal cues about satiation. The Chicagoans, in contrast, were more likely to follow rules linked to external factors, such as “Stop eating when I run out of a beverage,” or “Stop eating when the TV show I’m watching is over.” Stopping rules that rely on internal cues— like when the food stops tasting good or you feel full— decrease the odds that people eat more than their body needs or even wants.

Stopping rules are particularly critical in situations when people tend to double down on a losing hand.

These three decision rules—boundary, prioritizing, and stopping—help provide guidelines on what to do—“what is acceptable to do, what is more, important to do, and what to stop doing.”

Doing Things Better

Process rules, in contrast to boundary rules, focus on how to do things better.

Process rules work because they steer a middle path between the chaos of too few rules that can result in confusion and mistakes, and the rigidity of so many rules that there is little ability to adapt to the unexpected or take advantage of new opportunities. Simply put, process rules are useful whenever flexibility trumps consistency.

The most widely used process rule is the how-to rule. How-to rules guide the basics of executing tasks, from playing golf to designing new products. The other process rules, coordination and timing, are special cases of how-to rules that apply in particular situations. Coordination rules center on getting something done when multiple actors—people, organizations, or nations—have to work together. These rules orchestrate the behaviors of, for example, schooling fish, Zipcar members, and content contributors at Wikipedia. In contrast, timing rules center on getting things done in situations where temporal factors such as rhythms, sequences, and deadlines are relevant. These rules set the timing of, for example, when to get up every day and when dragonflies migrate.

87. Billy Beane on Making Better Decisions, Challenging Entrenched Thinking, and Avoiding Biases

Billy Beane was put in the spotlight when Brad Pitt played him in the movie rendition of Moneyball: The Art of Winning an Unfair Game.

Sports fans, however, knew long before Moneyball that Beane was special. He's the guy credited with taking a low budget team and turning them around by challenging the fundamental notions of a sport that had been around 150 years.

In a fascinating interview given on stage at the RSA conference in April 2015, Beane offered advice on how to make good decisions by challenging organizational norms, effectively using data, and avoiding biases.

When asked about pushing through entrenched thinking, Beane replied:

I sort of represented that entrenched thinking in some respect, because I was the guy who came up in the business – a business that was 150 years old – as a former player. Quite frankly, I had a great mentor, a gentleman who didn't come up in the industry, in Sandy Alderson.

When I hired, I made sure I looked outside at somebody who didn't have the experience bias with my first, and maybe even one of the best hires I ever had was Paul DePodesta, who was a Harvard Econ major, didn't play sports, and really, was able to come in and look at things with an eye that wasn't biased.

We also took ideas from people outside the industry, guys like Bill James and Sean Cook and applied them.

On how biases creep into our thought process no matter how old we are or in what industry we operate, Beane commented on taking the emotion out of the decision-making process and making it more rational.

Your own experiences, particularly in sports, where that experience may also be tied to an emotion as well, you tend to say, in football or soccer, in soccer there's a goal, and not all goals are created in terms of how you emotionally react to them. Baseball's a little bit the same way. So you kind of have to take a blind eye and look at things from the start and not make assumptions.

For us, we ultimately wanted to take all the emotion out of our decision making, and that came, many times, with your own experience.

One way to do that is to let data help you make decisions.

But data is everywhere and cheap. How can we leverage data analytics and extract meaningful information? On this Beane advocates an approach that makes sure you have cognitive diversity in the room – in other words, people that wouldn't normally be there.

[T]he book was really based on public information, as I said. Bill James had been writing for years, but because they didn't come up in the industry, it really was never applied.

Again, sports is very emotional. Very much, you have to come pass the eye test. What we wanted to do was make sure our eyes weren't fooling us.

As far as today, the game and sports has changed dramatically. In fact, looking at the book now, it feels like you're watching an episode of "The Flintstones" a little bit when you see some of this stuff. The only thing that I haven't changed is making sure that I bring in guys that normally wouldn't be in this room. The advantage I have is I have access to intellectual capital that normally would be in this room, but want to work for a sports team. We have access to data, everything ... was being measured, thrown into this huge vat of data, and it's up to my staff to sift through what has relevance and which doesn't as it applies to predicting player performance.

One of the keys to looking at data is to bring different lenses to it to gain insight. You also need to put processes and systems in place with respective feedback loops to make sure you're not a sucker—that is, you can distinguish between luck and skill.

You're constantly evaluating. Sometimes, even when you have success, there's an assumption that that success was based on your process. Actually, you're always analyzing your process, making sure that the reason you weren't correct wasn't through serendipity, but the reason was because you have a good process and you're doing things properly.

It's challenging because the business of sports has become very, very intelligent. Baseball teams, football teams, basketball teams, they're all using this, and hiring, once again, guys that normally would probably be in this room.

The world is always changing as its a dynamic system. Your processes need to be adaptive. Static processes in a dynamic world lead to extinction.

[T]here's so many variables in sports, too. We try and quantify things that you don't think you can quantify, things that people... Once again, when you talk about challenging assumptions, things that people assume can't be quantified.

You try and quantify them so, at least, you're creating a process that, more than anything, when you are right or wrong, you can at least go back and look and see why you were right or wrong, similar to a mathematical equation.

Beane found a way to challenge assumptions and in so doing gain insight that he had the courage (and authority) to put into practice. How did he change the way things were done? *Well, sometimes you don't. Early on in our process, we lost employees because there certainly wasn't a belief. Now, understand, when we started out we had a great platform. We were challenged from revenue standpoint, so it was an opportunity in some sense, and we really had no other way to operate.*

Through the course of doing things this way, we certainly lost people, but in the same sense, another year later we would gain two more people who were interested in going down this road. For us, it was rational. It made sense, and we really had no other choice. But, as Keynes so aptly put it "Worldly wisdom teaches us that it is better for the reputation to fail conventionally than to succeed unconventionally." And that path was not a linear story to success. There were moments when he doubted himself and operating in a cut-throat industry probably didn't make things easier. All eyes were on him. Was there pressure to go back to the way things were always done?

Unfortunately, probably for some A's fans. They probably doubted me more than I (did). I think the one thing about the process, it was like a math equation. At least we knew why we were doing something. Our other option, to us, didn't make much sense. Certainly, you're hoping you're going in the right direction, and the assumption is that you are. We felt like that was the best road that we could travel.

I think, if anything, we certainly didn't fear failure, because we felt like going a traditional path was certainly the surest of failure, based on our revenues and the payroll that we were on. We had a lot of autonomy, too. Autonomy within, we were given a budget. The only limitations we had in terms of our intellectual curiosity was really making sure we stayed in the budget our ownership gave us. "Listen, hey, do what you want to do, but make sure you stay within the lines a little bit."

But again, the fear... We knew going down another subjective path, we were certain to fail. We weren't going to consistently put something together that was on a year by year basis. The fear of going that route, there was greater fear going that route than going an objective route.

As a leader, it was Beane's job to make sure the strategy they were using to find under-rated players was embedded throughout the organization.

At times it was challenging, because we hired some really... I was a former baseball player, and a lot of guys who had come up in the business, the guys we were bringing in were guys with PhDs in behavioral economics and Harvard masters in statistics, and things like that. Bridging that gap initially was challenging because most, certainly a baseball player like myself, my default position isn't to run a regression log.

We operate in a world with tremendous amounts of data and information, but we're not challenging the platform that we're starting with to the extent we should be.

Even with a very young and progressive group of thinkers that are around me, with a little bit of experience, you will always start at a platform that you assume to be true based on previous success. We always have to analyze our foundation because very quickly a culture and a tradition of doing things can get ingrained in a very short period of time. If you assume from a false platform that you're correct, you can go really awry. For us, it is constantly...Also, not being wrapped up in your own hubris with success and understanding that even with an objective based decision making, you are not going to be right 100 percent of the time.

88. How Situations Influence Decisions

Michael Mauboussin, the first guest on our podcast, [The Knowledge Project](#), explains how our situations influence our decisions enormously in [Think Twice: Harnessing the Power of Counterintuition](#).

Mistakes born out of situations are difficult to avoid, in part because the influences on us are operating at a subconscious level. “Making good decisions in the face of subconscious pressure,” Mauboussin writes, “requires a very high degree of background knowledge and self-awareness.”

How do you feel when you read the word “treasure”? Do you feel good? What images come to mind? If you are like most people, just ruminating on “treasure” gives you a little lift. Our minds naturally make connections and associate ideas. So if someone introduces a cue to you— a word, a smell, a symbol— your mind often starts down an associative path. And you can be sure the initial cue will color a decision that waits at the path’s end. All this happens outside of your perception.

People around us also influence our decisions, often with good reason. Social influence arises for a couple of reasons. The first is asymmetric information, a fancy phrase meaning someone knows something you don’t. In those cases, imitation makes sense because the information upgrade allows you to make better decisions.

Peer pressure, or the desire to be part of the in-group, is a second source of social influence. For good evolutionary reasons, humans like to be part of a group— a collection of interdependent individuals— and naturally spend a good deal of time assessing who is “in” and who is “out.” Experiments in social psychology have repeatedly confirmed this. We explain behavior based on an individual’s choices and disposition and not the situation. That is, we associate bad behavior with the person and not the situation. Unless, of course, we’re talking about ourselves. This is “the fundamental attribution error”, a phrase coined by Lee Ross, a social psychologist at Stanford University.

There are two sides to this sword as the power of situations can work for good and evil. “Some of the greatest atrocities known to mankind,” Mauboussin writes, “resulted from putting normal people into bad situations.”

We believe our choices are independent of circumstance, however, the evidence points in another direction.

Some Wine With Your Music?

Consider how something as simple as the music playing in a store influences what wine we purchase.

Imagine strolling down the supermarket aisle and coming upon a display of French and German wines, roughly matched for price and quality. You do some quick comparisons, place a German wine in your cart, and continue shopping. After you check out, a researcher approaches and asks why you bought the German wine. You mention the price, the wine’s dryness, and how you anticipate it will go nicely with a meal you are planning. The researcher then asks whether you noticed German music playing and whether it had any bearing on your decision. Like most, you would acknowledge hearing the music and avow that it had nothing to do with your selection.

But this isn’t a hypothetical, it’s an actual study and the results affirm that the environment influences our decisions.

In this test, the researchers placed the French and German wines next to each other, along with small national flags. Over two weeks, the scientists alternated playing French accordion music and German Bierkeller pieces and watched the results. When French music played, French wines represented 77 percent of the sales. When German music played, consumers selected German wines 73 percent of the time. (See the image below) The music made a huge difference in shaping purchases. But that’s not what the shoppers thought.

While the customers acknowledged that the music made them think of either France or Germany, 86 percent denied the tunes had any influence on their choice.

Music subconsciously shaped purchase decisions

Source: Based on data from Adrian C. North, David J. Hargreaves, and Jennifer McKendrick, "In-store Music Affects Product Choice," *Nature* 390 (November 13, 2007), 13.

This is an example of priming, which psychologists formally define as “the incidental activation of knowledge structures by the current situational context.”¹ and priming happens all the time. For priming to be most effective it must have a strong connection to our situation’s goals.

Another example of how situations influence us is the default. In a fast moving world of non-stop bits and bytes the default is the path of least resistance — that is, it’s the system one option. To move away from the default is labor-intensive on our brains. Studies have repeatedly shown that most people go with defaults.

This applies to a wide array of choices, from insignificant issues like the ringtone on a new cell phone to consequential issues like financial savings, educational choice, and medical alternatives. Richard Thaler, an economist, and Cass Sunstein, a law professor, call the relationship between choice presentation and the ultimate decision “choice architecture.” They convincingly argue that we can easily nudge people toward a particular decision based solely on how we arrange the choices for them.

One context for decision making is how choices are structured. Knowing that many people opt for the default option, we can influence (for better or worse) large groups of people. Mauboussin relates a story about a prominent psychologist popular on the speaking circuit that “underscores how underappreciated choice architecture remains.”

When companies call to invite him to speak, he offers them two choices. Either they can pay him his set fee and get a standard presentation, or they can pay him nothing in exchange for the opportunity to work with him on an experiment to improve choice

architecture (e.g., redesign a form or Web site). Of course, the psychologist benefits by getting more real-world results on choice architecture, but it seems like a pretty good deal for the company as well, because an improved architecture might translate into financial benefits vastly in excess of his speaking fee. He noted ruefully that so far not one company has taken him up on his experiment offer.

(As a brief aside, I engage in public speaking on a fairly regular basis. I've toyed with similar ideas. Once I even went as far as offering to speak for no pre-set fee, only "value added" as judged by the client. They opted for the fee.)

Another great example of how environments affect behavior is Stanley Milgram's famous experiment on obedience to authority. "Ordinary people, simply doing their jobs, and without any particular hostility on their part, can become agents in a terrible destructive process," wrote Stanley Milgram.

[quote]Situations are generally more powerful than we think[/quote]

The key point is that situations are generally more powerful than we think and we can do things to resist the pull of "unwelcome social influence."

Mauboussin offers four tips:

1. Be aware of your situation.

You can think of this in two parts. There is the conscious element, where you can create a positive environment for decision making in your own surroundings by focusing on process, keeping stress to an acceptable level, being a thoughtful choice architect, and making sure to diffuse the forces that encourage negative behaviors.

Then there is coping with the subconscious influences. Control over these influences requires awareness of the influence, motivation to deal with it, and the willingness to devote attention to address possible poor decisions. In the real world, satisfying all three control conditions is extremely difficult, but the path starts with awareness.

2. Consider the situation first and the individual second.

This concept, called attributional charity, insists that you evaluate the decisions of others by starting with the situation and then turning to the individuals, not the other way around. While easier for Easterners than Westerners, most of us consistently underestimate the role of the situation in assessing the decisions we see others make. Try not to make the fundamental attribution error.

3. Watch out for the institutional imperative.

Warren Buffett, the celebrated investor and chairman of Berkshire Hathaway, coined the term institutional imperative to explain the tendency of organizations to "mindlessly" imitate what peers are doing. There are typically two underlying drivers of the imperative. First, companies want to be part of the in-group, much as individuals do. So if some companies in an industry are doing mergers, chasing growth, or expanding geographically, others will be tempted to follow. Second are incentives. Executives often reap financial rewards by following the group. When decision makers make money from being part of the crowd, the draw is nearly inescapable.

One example comes from a Financial Times interview with the former chief executive officer of Citigroup Chuck Prince in 2007, before the brunt of the financial crisis. "When the music stops, things will be complicated," offered Prince, demonstrating that he had some sense of what was to come. "But as long as the music is playing, you've got to get up and dance." The institutional imperative is rarely a good dance partner.

4. Avoid inertia.

Periodically revisit your processes and ask whether they are serving their purpose.

Organizations sometimes adopt routines and structures that become crystallized, impeding positive change. Efforts to reform education in the United States, for example, have been met with resistance from teachers and administrators who prefer the status quo.

We like to think that we're better than the situation, that we follow the decision-making process and rationally weigh the facts, consider alternatives, and determine the best course of action. While others are easily influenced, we are not. This is how we're wrong. Decision making is fundamentally a social exercise, something I cover in my Re:Think Decision Making workshop.

89. Making Decisions in a Complex Adaptive System

Simple description of a complex adaptive system

In Think Twice: Harnessing the Power of Counterintuition, Mauboussin does a good job adding to the work we've already done on complex adaptive systems:

You can think of a complex adaptive system in three parts (see the image at the top of this post). First, there is a group of heterogeneous agents. These agents can be neurons in your brain, bees in a hive, investors in a market, or people in a city. Heterogeneity means each agent has different and evolving decision rules that both reflect the environment and attempt to anticipate change in it. Second, these agents interact with one another, and their interactions create structure—scientists often call this emergence. Finally, the structure that emerges behaves like a higher-level system and has properties and characteristics that are distinct from those of the underlying agents themselves. ... The whole is greater than the sum of the parts.

The inability to understand the system based on its components prompted Nobel Prize winner and physicist Philip Anderson, to draft the essay, "More Is Different." Anderson wrote, "The behavior of large and complex aggregates of elementary particles, it turns out, is not to be understood in terms of the simple extrapolation of the properties of a few particles. Instead, at each level of complexity entirely new properties appear."

Mauboussin comments that we are fooled by randomness:

The problem goes beyond the inscrutable nature of complex adaptive systems. Humans have a deep desire to understand cause and effect, as such links probably conferred humans with evolutionary advantage. In complex adaptive systems, there is no simple method for understanding the whole by studying the parts, so searching for simple agent-level causes of system-level effects is useless. Yet our minds are not beyond making up a cause to relieve the itch of an unexplained effect. When a mind seeking links between cause and effect meets a system that conceals them, accidents will happen.

Misplaced Focus on the Individual

One mistake we make is extrapolating the behaviour of an individual component, say an individual, to explain the entire system. Yet when we have to solve a problem dealing with a complex system, we often address an individual component. In so doing, we ignore Garrett Hardin's first law of Ecology, you can never do merely one thing and become a fragilista.

That unintended system-level consequences arise from even the best-intentioned individual-level actions has long been recognized. But the decision-making challenge remains for a couple of reasons. First, our modern world has more interconnected systems

than before. So we encounter these systems with greater frequency and, most likely, with greater consequence. Second, we still attempt to cure problems in complex systems with a naïve understanding of cause and effect.

When I speak with executives from around the world going through a period of poor performance, it doesn't take long for them to mention they want to hire a star from another company. "If only we had Kate," they'll say, "we could smash the competition and regain our footing."

At first, poaching stars from competitors or even teams within the same organization seems like a winning strategy. But once the star comes over the results often fail to materialize.

What we fail to grasp is that their performance is part of an ecosystem and removing them from that ecosystem — that is isolating the individual performance — is incredibly hard without properly considering the entire ecosystem. (Reversion to the mean also likely accounts for some of the star's fading as well).

Three Harvard professors concluded, "When a company hires a star, the star's performance plunges, there is a sharp decline in the functioning of the group or team the person works with, and the company's market value falls."

If it sounds like a lot of work to think this through at many levels, it should be. Why should it be easy?

Another example of this at an organizational level has to do with innovation. Most people want to solve the innovation problem. Ignoring for a second that that is the improper framing, how do most organizations go about this? They copy what the most successful organizations do. I can't count the number of times the solution to an organization's "innovation problem" is to be more like Google. Well-intentioned executives blindly copy approaches by others such as 20% innovation time, without giving an ounce of thought to the role the ecosystem plays.

Isolating and focusing on an individual part of a complex adaptive system without an appreciation and understanding of that system itself is sure to lead to disaster.

What Should We Do?

So this begs the question, what should we do when we find ourselves dealing with a complex adaptive system? Mauboussin provides three pieces of advice:

1. Consider the system at the correct level.

Remember the phrase "more is different." The most prevalent trap is extrapolating the behavior of individual agents to gain a sense of system behavior. If you want to understand the stock market, study it at the market level. Consider what you see and read from individuals as entertainment, not as education. Similarly, be aware that the function of an individual agent outside the system may be very different from that function within the system. For instance, mammalian cells have the same metabolic rates in vitro, whether they are from shrews or elephants. But the metabolic rate of cells in small mammals is much higher than the rate of those in large mammals. The same structural cells work at different rates, depending on the animals they find themselves in.

2. Watch for tightly coupled systems.

A system is tightly coupled when there is no slack between items, allowing a process to go from one stage to the next without any opportunity to intervene. Aircraft, space missions, and nuclear power plants are classic examples of complex, tightly coupled systems. Engineers try to build in buffers or redundancies to avoid failure, but frequently don't anticipate all possible contingencies. Most complex adaptive systems are loosely coupled, where removing or incapacitating one or a few agents has little impact on the system's performance. For example, if you randomly remove some investors, the stock market will continue to function fine. But when the agents lose diversity and behave in a coordinated

fashion, a complex adaptive system can behave in a tightly coupled fashion. Booms and crashes in financial markets are an illustration.

3. Use simulations to create virtual worlds.

Dealing with complex systems is inherently tricky because the feedback is equivocal, information is limited, and there is no clear link between cause and effect. Simulation is a tool that can help our learning process. Simulations are low cost, provide feedback, and have proved their value in other domains like military planning and pilot training.

90. Focusing Illusions

My favorite chapter in the book Rapt: Attention and the Focused Life by Winifred Gallagher is called 'Decisions: Focusing Illusions.' It's a really great summary of how focusing on the wrong things affects the weights we use to make decisions. There is a lot of great content packed into this chapter but I'll attempt to highlight a few points.

Bounded Rationality

According to the principle of 'bounded rationality,' which (Daniel) Kahneman first applied to economic decisions and more recently to choices concerning quality of life, we are reasonable-enough beings but sometimes liable to focus on the wrong things. Our thinking gets befuddled not so much by our emotions as by our 'cognitive illusions,' or mistaken intuitions, and other flawed, fragmented mental constructs.

Loss/Risk Aversion

If you're pondering a choice that involves risk, you might focus too much on the threat of possible loss, thereby obscuring an even likelier potential benefit. Where this common scenario is concerned, research shows that we aren't so much risk-averse as loss-averse, in that we're generally much more sensitive to what we might have to give up than to what we might gain.

The Focusing Illusion

The key to understanding why you pay more attention to your thoughts about living than to life itself is neatly summed up by what Kahneman proudly calls his 'fortune cookie maxim' (a.k.a the focusing illusion): 'Nothing in life is as important as you think it is while you are thinking about it.' Why? 'Because you're thinking about it!'

In one much-cited illustration of the focusing illusion, Kahneman asked some people if they would be happier if they lived in California. Because the climate is often delightful there, most subjects thought so. For the same reason, even Californians assume they're happier than people who live elsewhere. When Kahneman actually measured their well-being however, Michiganders and others are just as contented as Californians. The reason is

that 99 percent of the stuff of life – relationships, work, home, recreation – is the same no matter where you are, and once you settle in a place, no matter how salubrious, you don't think about it's climate very much. If you're prompted to evaluate it, however, the weather immediately looms large, simply because you're paying attention to it. This illusion inclines you to accentuate the difference between Place A and Place B, making it seem to matter much more than it really does, which is marginal.

To test the fortune cookie rule, you have only to ask yourself how happy you are. The question automatically summons your remembering self, which will focus on any recent change in your life – marriage or divorce, new job or home. You'll then think about this novel event, which in turn will increase its import and influence your answer. If you're pleased that you've just left the suburbs for the city, say, you'll decide that life is pretty good. If you regret the move, you'll be dissatisfied in general. Fifteen years on, however, the change that looms so large now will pale next to a more recent event – a career change, perhaps or becoming a grandparent – which will draw your focus and, simply because you're thinking about it, bias your evaluation of your general well-being.

The Effects of Adaptation

Like focusing too much on the opinions of your remembering self, overlooking the effects of adaptation – the process of becoming used to a situation – can obstruct wise decisions about how to live. As Kahneman says, 'when planning for the future, we don't consider that we will stop paying attention to a thing.'

The tendency to stop focusing on a particular event or experience over time, no matter how wonderful or awful, helps explain why the differences in well-being between groups of people in very different circumstances tend to be surprisingly small – sometimes astoundingly so. The classic examples are paraplegics and lottery winners, who respectively aren't nearly as miserable or happy as you'd think. 'That's where attention comes in,' says Kahneman. 'People think that if they win the lottery, they'll be happy forever. Of course, they will not. For a while, they are happy because of the novelty, and because they think about winning all the time. Then they adapt and stop paying attention to it.' Similarly, he says, 'Everyone is surprised by how happy paraplegics can be, but they are not paraplegic full-time. They do other things. They enjoy their meals, their friends, the newspaper. It has to do with the allocation of attention.'

Like couples who've just fallen in love, professionals starting a career, or children who go to camp for the first time, paraplegics and lottery winners initially pay a lot of attention to their new situation. Then, like everybody else, they get used to it and shift their focus to the next big thing. Their seemingly blase attitude surprises us, because when we imagine ourselves in their place, we focus on how we'd feel at the moment of becoming paralyzed or wildly rich, when such an event utterly monopolizes one's focus. We forget that we, too, would get used to wealth, a wheelchair, and most other things under the sun, then turn our attention elsewhere.

Good Enough

Finally, don't worry if the choice you made wasn't the absolute best, as long as it meets your needs. Offering the single most important lesson from his research, Schwartz says, 'Good enough is almost always good enough. If you have that attitude, many problems about decisions and much paralysis melt away.'

91. The Pursuit of Worldly Wisdom

Charlie Munger, the billionaire business partner of Warren Buffett and a major inspiration behind this site, is not only one of the best investors the world has witnessed, but he's also one of the best thinkers. A quick recap is in order.

Munger has illuminated timeless wisdom in the minds' search algorithm, Academic Economics, stretch goals, mental models, the value of thinking backward and forward, problem-solving, partnerships, and inversion among others.

What is elementary, worldly wisdom? Well, the first rule is that you can't really know anything if you just remember isolated facts and try and bang 'em back. If the facts don't hang together on a latticework of theory, you don't have them in a usable form.

— Charlie Munger

He's even offered two sets of book recommendations.

In his book, *Charlie Munger: The Complete Investor*, which has become my new go-to recommendation for people interested in an introduction to Munger's thinking, Tren Griffin lays out Munger's path to worldly wisdom.

Munger has adopted an approach to business and life that he refers to as worldly wisdom. Munger believes that by using a range of different models from many different disciplines—psychology, history, mathematics, physics, philosophy, biology, and so on—a person can use the combined output of the synthesis to produce something that has more value than the sum of its parts. Robert Hagstrom wrote a wonderful book on worldly wisdom entitled Investing: The Last Liberal Art, in which he states that “each discipline entwines with, and in the process strengthens, every other. From each discipline the thoughtful person draws significant mental models, the key ideas that combine to produce a cohesive understanding. Those who cultivate this broad view are well on their way to achieving worldly wisdom.”

It is clear that Munger loves to learn. He actually has fun when he is learning, and that makes the worldly wisdom investing process enjoyable for him. This is important because many people do not find investing enjoyable, especially when compared to gambling, which science has shown can generate pleasure via chemicals (e.g., dopamine) even though it is an activity with a negative net present value. What Munger has done is created a system—worldly wisdom—that allows him to generate the same chemical rewards in an activity that has a positive net present value. When you learn something new, your brain gives itself a chemical reward, which motivates you to do the work necessary to be a successful investor. If you do this work and adopt a worldly wisdom mindset, Munger believes you will create an investing edge over other investors.

You've got to have models in your head. And you've got to array your experience—both vicarious and direct—on this latticework of models.

— charlie munger

Munger used a latticework of mental models in developing his approach. Herbert Simon, in his autobiography, *Models of My Life*, captured the idea of a mental model when he said: *A large part of the difference between the experienced decision maker and the novice in these situations is not any particular intangible like “judgment” or “intuition.” If one could open the lid, so to speak, and see what was in the head of the experienced decision maker, one would find that he had at his disposal repertoires of possible actions; that he had checklists of things to think about before he acted; and that he had mechanisms in his mind to evoke these, and bring these to his conscious attention when the situations for decisions arose.*

Latticework of Mental Models

Munger carefully chose the latticework model, to convey the idea that things are interconnected. We need more than a deep understanding of one segment, we need a working knowledge of all of them and how they interact and link. This is conveyed by the Japanese proverb “The frog in a well knows nothing of the mighty ocean.”

In *Charlie Munger: The Complete Investor*, Griffin continues:

Understanding the worldly wisdom methodology is made easier if you see it applied in an example. To illustrate the method, Munger gave the example of a business that raises the price of its product and yet sells more of that product. This would appear to violate the rule of supply and demand as taught in economics. However, if one thinks about the discipline of psychology, one might conclude that the product is a Giffen good, which people desire more of at higher prices. Or one could conclude that low prices signal poor quality to buyers and that raising prices will result in more sales. Alternatively, you can look for bias caused by incentives and discover that what has actually happened in his example is that the seller has bribed the purchasing agents of the purchasers.

Munger described a situation in which this actually happens:

Suppose you're the manager of a mutual fund, and you want to sell more. People commonly come to the following answer: You raise the commissions which, of course, reduces the number of units of real investments delivered to the ultimate buyer, so you're increasing the price per unit of real investment that you're selling the ultimate customer. And you're using that extra commission to bribe the customer's purchasing agent. You're bribing the broker to betray his client and put the client's money into the high-commission product.

While we can't know everything, we can know the big ideas from multiple disciplines. We don't want to be the frog. This is one way we can add value in the decision-making process and it allows for the effective use of what I call the Munger two-step.

“Simply put,” Griffin writes, “Munger believes that people who think very broadly and understand many different models from many different disciplines make better decisions.”

In a 2003 speech at UCB Business School entitled Academic Economics — Strengths and Weaknesses, after Considering Interdisciplinary Needs, Munger said:

You've got a complex system and it spews out a lot of wonderful numbers that enable you to measure some factors. But there are other factors that are terribly important, [yet] there's no precise numbering you can put to these factors. You know they're important, but you don't have the numbers. Well, practically (1) everybody overweighs the stuff that can be numbered, because it yields to the statistical techniques they're taught in academia, and (2) doesn't mix in the hard-to-measure stuff that may be more important. That is a mistake I've tried all my life to avoid, and I have no regrets for having done that.

Worldly Wisdom

Griffin continues:

In Munger's view, it is better to be worldly wise than to spend lots of time working with a single model that is precisely wrong.

A multiple-model approach that is only approximately right will produce a far better outcome in anything that involves people or a social system. While making the case for a lattice of mental models approach (described here shortly), Robert Hagstrom pointed out that Munger is providing support for those who advocate for a wide-ranging liberal arts education.

Munger would be what the poet Archilochus calls a fox. The ancient Greeks said “The fox knows many things; the hedgehog one great thing.”

The theory of modern education is that you need a general education before you specialize. And I think to some extent, before you're going to be a great stock picker, you need some general education.

— Charlie Munger

Commenting on Munger, former Microsoft CEO Bill Gates said, “(he) is truly the broadest thinker I have ever encountered.” Buffett added that Munger has “the best 30-second mind in the world. He goes from A to Z in one move. He sees the essence of everything before you even finish the sentence.”

How does Munger do this? That’s a question worth slowing down and thinking about.

You have to realize the truth of biologist Julian Huxley’s idea that ‘Life is just one damn relatedness after another.’ So you must have the models, and you must see the relatedness and the effects from the relatedness.

— Charlie Munger

Where do we get these ideas?

We let history be our guide. If one way to ensure you make poor decisions is to use a small sample size, we can reason that we should seek out the biggest sample sizes we can.

What crosses most of history? Biology, Chemistry, Physics. And of course, throw in some Psychology so we can better understand how we are led astray.

Thinking

Griffin continues:

Munger’s breadth of knowledge is something that is naturally part of his character but also something that he intentionally cultivates. In his view, to know nothing about an important subject is to invite problems. Both Munger and Buffett set aside plenty of time each day to just think. Anyone reading the news is provided with constant reminders of the consequences of not thinking. Thinking is a surprisingly underrated activity. Researchers published a study in 2014 that revealed that approximately a quarter of women and two-thirds of men chose electric shocks over spending time alone with their own thoughts.

If you can’t be alone with your thoughts, you don’t deserve them. We try to run away from the pain of thinking. Instead, we turn to the instant gratification of Netflix.

Munger’s speeches and essays are filled with the thoughts of great people from the past and present from many different domains. Munger is also careful to set aside a lot of time in his schedule for reading. To say he loves books is an understatement. Buffett has said that Munger has read hundreds of biographies, as just one example. He is very purposeful in his approach to worldly wisdom, preferring not to fill his calendar with appointments and meetings.

When talking about how to get smarter, Buffett said: “You could hardly find a partnership in which two people settle on reading more hours of the day than in ours.” Adding, “Look, my job is essentially just corralling more and more and more facts and information, and occasionally seeing whether that leads to some action.”

This is where we go astray so easily. It’s easy to think about our own discipline, the one we live in on a daily basis. This comes naturally. However, it’s likely to lead to problems. We become the proverbial man with a hammer, “To the man with a hammer everything looks like a nail. If you only have one model you will fit whatever problem you face to the model you have.” It’s hard work to think. That’s why so few people seem to take this passage. But it should be hard, otherwise, it would be too easy.

I believe in the discipline of mastering the best that other people have ever figured out. I don’t believe in just sitting down and trying to dream it all up yourself. Nobody’s that smart.

— Charlie Munger

A Multidisciplinary Approach

The tagline for this website: Mastering the best of what other people have already figured out, comes from the Munger quote above.

Griffin continues:

It is critical for a person who desires to be wise to think broadly and learn from others. Munger has said many times that someone who is really smart but has devoted all of their time to being an expert in a narrow area may be dangerous to themselves and others. Examples of this include macroeconomists who study the economy but are disastrous when investing their own portfolios and marketing experts who may think that most all business problems can be solved through marketing. Financiers tend to think similarly about their own profession. Too many people believe that what they do at work is hard and what others do is easy.

The best approach is the multi-disciplinary one, Munger argues:

You may say, "My God, this is already getting way too tough." But, fortunately, it isn't that tough—because eighty or ninety important models will carry about 90 percent of the freight in making you a worldly wise person. And, of those, only a mere handful really carry very heavy freight.

"This reference to eighty or ninety important models" Griffin writes, "has caused people to ask Munger for a complete list of these important models."

While Munger identified many models in the discipline of psychology in his famous The Psychology of Human Misjudgment speech and mentioned other models on an ad-hoc basis, he has never prepared a complete list covering all disciplines.

Munger believes that by learning to recognize certain dysfunctional decision-making processes, an investor can learn to make fewer mistakes. He also believes that no matter how hard someone works and learns, mistakes cannot be completely eliminated. The best one can hope for is to reduce their frequency and, hopefully, their magnitude.

Munger elaborates in a 1995 speech at Harvard University:

Man's imperfect, limited-capacity brain easily drifts into working with what's easily available to it. And the brain can't use what it can't remember or when it's blocked from recognizing because it's heavily influenced by one or more psychological tendencies bearing strongly on it ... the deep structure of the human mind requires that the way to full scope competency of virtually any kind is to learn it all to fluency—like it or not.

In a 2007 speech at USC law school, Munger says:

I constantly see people rise in life who are not the smartest, sometimes not even the most diligent, but they are learning machines. They go to bed every night a little wiser than they were when they got up, and boy, does that help, particularly when you have a long run ahead of you. ... So if civilization can progress only with an advanced method of invention, you can progress only when you learn the method of learning. Nothing has served me better in my long life than continuous learning. I went through life constantly practicing (because if you don't practice it, you lose it) the multidisciplinary approach and I can't tell you what that's done for me. It's made life more fun, it's made me more constructive, it's made me more helpful to others, and it's made me enormously rich. You name it, that attitude really helps.

Back to Griffin, writing in Charlie Munger: The Complete Investor, who says:

In looking at a decision, Munger believes that it is wise to ask questions. Have dysfunctional decision-making heuristics from psychology caused an error? Are there approaches one can use to find those mistakes? Munger likes to use a model from algebra and invert problems to find a solution. Looking for models that can reveal and explain mistakes so one can accumulate worldly wisdom is actually lots of fun. It is like a puzzle to be solved.

A lattice approach is, in effect, a double-check on the investing process. But instead of just two checks, you are checking the result over and over. Munger believes that by going over your decision-making process and carefully using skills, ideas, and models from many disciplines, you can more consistently not be stupid. You will always make some bone-

headed mistakes even if you're careful, but his process is designed to decrease the probability of those mistakes.

Munger likes checklists to ensure he is taking advantage of as many models as possible. At the 2002 Berkshire Hathaway annual meeting, Munger said: "You need a different checklist and different mental models for different companies. I can never make it easy by saying, "Here are three things." You have to derive it yourself to ingrain it in your head for the rest of your life."

Learning From Mistakes

An aspect of Munger's approach is learning from your mistakes. I've made more than my fair share of them.

I like people admitting they were complete stupid horses' asses. I know I'll perform better if I rub my nose in my mistakes. This is a wonderful trick to learn.

— Charlie Munger

Griffin writes:

Munger has said repeatedly that he made more mistakes earlier in life than he is making now. One of his early mistakes was to own a company that made electrical transformers. He has also said that he has found himself in real estate ventures that would only be enjoyed by a masochist. He seems to have more tolerance for mistakes in real estate than other areas of business. The idea of building things as opposed to just trading stocks has a particular appeal to Munger.

Munger believes that one great way to avoid mistakes is to own a business that is simple to understand, given your education and experience. He pointed out: "Where you have complexity, by nature you can have fraud and mistakes." This approach echoes the view of Buffett, who likes challenges that are the business equivalent of netting fish in a barrel. Buffett has said that if you cannot explain why you failed after you have made a mistake, the business was too complex for you. In other words, Munger and Buffett like to understand why they made a mistake so they can learn from the experience. If you cannot understand the business, then you cannot determine what you did wrong. If you cannot determine what you did wrong, then you cannot learn. If you cannot learn, you will not know what you're doing, which is the real cause of risk.

Forgetting your mistakes is a terrible error if you're trying to improve your cognition. Reality doesn't remind you. Why not celebrate stupidities in both categories?

— Charlie munger

Griffin concludes:

Munger has chosen the word wisdom purposefully because he believes that mere knowledge, especially from only one domain, is not enough. To be wise, one must also have experience, common sense, and good judgment. How one actually applies these things in life is what makes a person wise.

92. Keeping Things Simple and Tuning out Folly

Keeping things simple makes a huge difference and yet we are drawn to the sexiness of complexity. Einstein was a master of sifting the essential from the non-essential.

And consider this from Charlie Munger: The Complete Investor:

Peter Bevelin's book Seeking Wisdom: From Darwin to Munger has a section on the importance of simplicity.

Bevelin advised: "Turn complicated problems into simple ones. Break down a problem into its components, but look at the problem holistically." Keeping things as simple as possible, but no more so, is a constant theme in Munger's public statements. In a joint letter to shareholders, Munger and Buffett once wrote: "Simplicity has a way of improving performance through enabling us to better understand what we are doing."

[...]

By focusing on finding decisions and bets that are easy, avoiding what is hard, and stripping away anything that is extraneous, Munger believes that an investor can make better decisions. By "tuning out folly" and swatting away unimportant things "so your mind isn't cluttered with them ... you're better able to pick up a few sensible things to do," said Munger. Focus enables both simplicity and clarity of thought, which in Munger's view leads to a more positive investing result.

"If something is too hard, we move on to something else. What could be simpler than that?"

— Charlie Munger

There is a compelling advantage in life to be found in exploiting unrecognized simplicities, something Peter Thiel tries to tease out in interviews. Essential to recognizing simplicity is scheduling time to think.

"We have three baskets: in, out, and too tough... We have to have a special insight, or we'll put it in the too tough basket."

— Charlie Munger

Simplicity is Filtering

William James said: "The art of being wise is the art of knowing what to overlook." And there are no truer words that have been spoken.

In Arthur Conan Doyle's The Reigate Puzzle, Sherlock Holmes says: "It is of the highest importance in the art of detection to be able to recognize, out of a number of facts, which are incidental and which vital."

And part of filtering is understanding what you know and what you don't know, that is, understanding your circle of competence.

"We have a passion for keeping things simple."

— Charlie Munger

In an interview with Jason Zweig, Munger said:

Confucius said that real knowledge is knowing the extent of one's ignorance. Aristotle and Socrates said the same thing. Is it a skill that can be taught or learned? It probably can, if you have enough of a stake riding on the outcome. Some people are extraordinarily good at knowing the limits of their knowledge, because they have to be. Think of somebody who's been a professional tightrope walker for 20 years—and has survived. He couldn't survive as a tightrope walker for 20 years unless he knows exactly what he knows and what he doesn't know. He's worked so hard at it, because he knows if he gets it wrong he won't survive. The survivors know.

Another time he offered:

Part of that [having uncommon sense], I think, is being able to tune out folly, as distinguished from recognizing wisdom. You've got whole categories of things you just bat away so your brain isn't cluttered with them. That way, you're better able to pick up a few sensible things to do.

Warren Buffett, the CEO of Berkshire Hathaway agrees:

Yeah, we don't consider many stupid things. I mean, we get rid of 'em fast.. Just getting rid of the nonsense — just figuring out that if people call you and say, "I've got this great, wonderful idea", you don't spend 10 minutes once you know in the first sentence that it isn't a great, wonderful idea... Don't be polite and go through the whole process.

And Peter Bevelin, writing in Seeking Wisdom, offers:

Often we try to get too much information, including misinformation, or information of no use to explain or predict. We also focus on details and what's irrelevant or unknowable and overlook the obvious truths. Dealing with what's important forces us to prioritize. There are often just a few actions that produce most of what we are trying to achieve. There are only a few decisions of real importance.

More information doesn't equal more knowledge or better decisions. And remember that today we not only have access to more information, but also misinformation.

And the harder we work at something the more confident we become.

It's worth pausing to reflect on three things at this point: 1) understanding and seeking simplicity; 2) dealing with the easy problems first; and 3) honing your skills by learning what to overlook and getting rid of bad ideas quickly (how many organizations do that!?)... this goes hand in hand with understanding your circle of competence.

92. The Biological Bases of Human Resilience

In Stronger: Develop the Resilience You Need to Succeed there is a section on the Biological Bases of Human Resilience that is fascinating.

It turns out the key to developing resilience at the biological level is to interpret experience in a way that increases performance and facilitates homeostasis. Changing attitudes and developing resilience through training is key. Optimism is your friend.

In 1975, neurologist Paul MacLean coined the term triune brain to describe its three functional levels: The neocortex is the most sophisticated component of the human brain, representing its highest functioning level. Not only does the neocortex interpret sensory signals, communications, and gross proprioceptive-based control of motor (musculoskeletal) behaviors, but part of it—the ventromedial prefrontal cortex (vmPFC)—presides over imagination, logic, decision making, problem solving, planning, apprehension, and, most important, the interpretation of experience.

It is the vmPFC that labels an experience (real or imagined) as threatening, punishing, or rewarding. It finds solutions to problems, it sees the opportunity in danger, and it sees the glass as half full rather than half empty. Based on the nature of the interpretation of experience, the vmPFC then activates the second level of the triune brain: the limbic system.

The limbic system is relevant in any discussion of stress and resilience because of its role as the human brain's emotional control center. The limbic system is believed to be just that, a system, consisting of numerous highly connected neural structures, for example, the hypothalamus, hippocampus, septum, cingulate gyrus, and the amygdala. The amygdala is the primary anatomic center for fear, anger, trauma, and aggression. It's also the center of the fight-or-flight response, a term coined by psychologist Walter Cannon in 1915. The amygdala serves as the primary survival mechanism in the human body. Thus, it's a key anatomic component in the biology of resilience.

The brain stem and spinal cord represent the lowest level of the triune brain. The major functions of this level are the maintenance of so-called vegetative roles such as heartbeat, respiration, vasomotor activity, and the conduction of impulses to many higher levels of the brain. The spinal cord represents the central pathway for neurons as they conduct signals to and from the brain. The brain stem is the basic engine that drives the machinery of the human body.

Human resilience represents a most elegant and ongoing dance between the vmPFC and the amygdala. When faced with danger, the vmPFC activates the amygdala so as to prepare you to fight, flee, or otherwise resolve the threat. Highly resilient people appear to be able to effectively regulate the amygdala so as to benefit from its activation but then allow it to quickly recover its baseline activity. This process of recovery to a steady state is what Cannon called "the reestablishment of homeostasis."

Consequently, the bodies of resilient people are supercharged with moderate increases in hormones such as adrenalin, noradrenalin, gamma-Aminobutyric acid, neuropeptide Y and Cortisol, which allow you to do "superhuman" things for short periods of time. When these hormones surge, your strength and perception

increase, your memory improves, your eyesight may get better, your tolerance for pain increases, and you react to stimuli faster. In other words, you're better prepared to meet any challenge success fully.

The person who is not resilient experiences homeostatic failure, during which the vmPFC interpretations either overstimulate or understimulate the limbic system. The result of overstimulation can be anxiety, panic attacks, confusion, reduced problem-solving capacity, irritability, anger, even violence (for example, road rage, airline rage), and seizures. The result of under stimulation may be hopelessness, depression, resentment, and a lack of motivation. With highly frequent or chronic overstimulation the amygdala can

develop a state of chronic hypersensitivity at the cellular level. Amygdaloid nerve cells literally become highly irritable and will over-respond to experiences that would have not otherwise caused excitation. It's like having 10 cups of coffee.

93. How People Make Big Decisions

We all go through psychological steps when we make big decisions. Some people call this the “existential cycle,” which really has four stages: doing, contemplating, preparing, and experimenting.

Echoing Tolstoy on regret avoidance, Sebastian Bailey and Octavius Black write in Mind Gym: Achieve More by Thinking Differently:

These four stages are much like exercises in risk management. No one wants to look back on his or her life at some point and say I wish I would have or If only I had.

While there are other ways, the existential cycle helps us make life changing decisions — like who to marry, where to work, and where to live.

The first stage, “doing,” is where you spend most of your life: It is your settled, equilibrium position. The doing may be all sorts of things— writing emails, riding horses, reading books, washing up, going to meetings, listening to lectures, cooking, dancing, running, sharing stories with friends, telling jokes, or making love. Of course, these are not done all at the same time (not unless you’re really talented). Whatever the activity may be, and however enjoyable or dull it is, you are doing it and it tends to keep you occupied.

Sometimes we get to “contemplating,” where we consider whether or how things would be different. What would life be like if you move to California? (Hint: It won’t make you happier.)

Then occasionally we move to “preparing.”

You search on the web for real estate agents in San Diego or Key West, find out what property prices are, check weather patterns, possibly even visit your preferred destination on your next vacation. You have moved beyond imagining how things could be different to investigating the practical options for how to make them different.

Finally you make the change.

You leave your job, buy a house, and move all your possessions. This stage is called “experimenting.” After you’ve settled in and started the beachside bar you’d dreamed about, this becomes your normal way of living, and you are once again in a state of doing. The process isn’t overly complicated or hard. The challenge becomes moving through it at the right pace in a way that aligns with your principles.

The Doing Magnet

As you travel around your cycle, you will have conversations with yourself that stop you from moving on to the next stage and instead take you back to doing.

Sometimes these thoughts can be very sensible and prevent you from wasting time or following the wrong path. But sometimes, unfortunately, they prevent you from both spotting and taking opportunities that could dramatically improve your life. The trick lies in recognizing the internal conversations and being able to make an informed decision about whether to listen to them or to ignore them and move on.

When the Doing Magnet is Weak

Irrational exuberance are those people who are forever saying things like I wish I hadn't rushed into that or If only I'd thought about it first. Rather than never crossing the Rubicon, they're happy to head over far too easily— without ever considering the size of the army on the other side. In terms of the existential cycle, their doing magnet is relatively weak—the centrifugal momentum of the next new thing is stronger than the gravitational force of the status quo.

If you find that you can't hold down a job, you can't keep a relationship, you spend money on a whim, or you haven't gotten around to making your home into a place you like living in, and you regret it, then you may be suffering from a form of irrational exuberance. The best advice in this situation is this: spend longer at the preparing stage before wading across your Rubicon.

For example, consider one of these choices:

- Think through all the possible disadvantages of taking this course of action as well as the advantages— really make an effort to present the case for caution on this occasion.*
- Contrast the allure of the new situation with how your existing life might improve even if you don't make this big change. People who are always moving on to new jobs often fail to consider how their current jobs could get better. A new job may be attractive, but it is wrong to assume the old one will stay the same. New possibilities could open up. What happens when your boss moves on?*
- Contemplate the bigger and better gains and pleasures you could have if you didn't always go for instant gratification. Could the gratification get more gratifying?*
- Consider any decisions you made in the past that led to situations you later regretted. What can you learn from these that will help you make a wiser decision this time.*

If you Want to Improve, you have to Cross the Rubicon

“Do. Or do not. There is no try.” — Yoda

You have a choice in how you run your life. There is no “can't,” only “will” and “won't.” The trick is knowing why you are, or aren't, moving around the existential cycle and, in particular, crossing your Rubicon. Like we've said, the right thing isn't to always cross or always not cross. The right thing is to understand why you want to cross or don't want to cross, and then make your decision.

Nevertheless, none of us want to live our lives in a constant state of doing. I might not be in good enough shape today to swim 2.4 miles, but that doesn't mean I won't be in the future. Plus, our reasons for remaining in one state may not be strong. At some point, in certain aspects of our lives, if we want to progress, we must cross the Rubicon.

A decision to not cross the Rubicon based on the wrong reasons— when catastrophic fantasies rule our mind-sets— is what causes people to look back on their lives and think If

only. ... All of us who have looked back and been proud of what we have done have crossed the Rubicon at least once and maybe many times.

There's a famous Latin maxim, carpe diem, which translated means "seize the day." The question you have to ask yourself is, When it comes to crossing Rubicons, just how much of a Caesar am I prepared to be?

94. Biases and Blunders

You would be hard pressed to come across a reading list on behavioral economics that doesn't mention Nudge: Improving Decisions About Health, Wealth, and Happiness by Richard Thaler and Cass Sunstein.

It is a fascinating look at how we can create environments or 'choice architecture' to help people make better decisions. But one of the reasons it's been so influential is because it helps us understand why people sometimes make bad decisions in the first place. If we really want to understand how we can nudge people into making better choices, it's important to understand why they often make such poor ones.

Let's take a look at how Thaler and Sunstein explain some of our common mistakes in a chapter aptly called 'Biases and Blunders.'

Anchoring and Adjustment

Humans have a tendency to put too much emphasis on one piece of information when making decisions. When we overweigh one piece of information and make assumptions based on it, we call that an anchor. Say I borrow a 400-page-book from a friend and I think to myself, the last book I read was about 300 pages and I read it in 5 days so I'll let my friend know I'll have her book back to her in 7 days. Problem is, I've only compared one factor related to me reading books and now I've made a decision without taking into account many other factors which could affect the outcome. For example, is the new book a topic I will digest at the same rate? Will I have the same time over those 7 days for reading? I have looked at number of pages but are the number of words per page similar?

As Thaler and Sunstein explain:

This process is called 'anchoring and adjustment.' You start with some anchor, the number you know, and adjust in the direction you think is appropriate. So far, so good. The bias occurs because the adjustments are typically insufficient.

Availability Heuristic

This is the tendency of our mind to overweigh information that is recent and readily available. What did you think about the last time you read about a plane crash? Did you start thinking about you being in a plane crash? Imagine how much it would weigh on your mind if you were set to fly the next day.

We assess the likelihood of risks by asking how readily examples come to mind. If people can easily think of relevant examples, they are far more likely to be frightened and concerned than if they cannot.

Accessibility and salience are closely related to availability, and they are important as well. If you have personally experienced a serious earthquake, you're more likely to believe that an earthquake is likely than if you read about it in a weekly magazine. Thus, vivid and easily imagined causes of death (for example, tornadoes) often receive inflated estimates of probability, and less-vivid causes (for example, asthma attacks) receive low estimates, even if they occur with a far greater frequency (here, by a factor of twenty). Timing counts too: more recent events have a greater impact on our behavior, and on our fears, than earlier ones.

Representativeness Heuristic

Use of the representativeness heuristic can cause serious misperceptions of patterns in everyday life. When events are determined by chance, such as a sequence of coin tosses, people expect the resulting string of heads and tails to be representative of what they think of as random. Unfortunately, people do not have accurate perceptions of what random sequences look like. When they see the outcomes of random processes, they often detect patterns that they think have great meaning but in fact are just due to chance.

It would seem as though we have issues with randomness. Our brains automatically want to see patterns when none may exist. Try a coin toss experiment on yourself. Simply flip a coin and keep track if it's heads or tails. At some point you will hit 'a streak' of either heads

or tails and you will notice that you experience a sort of cognitive dissonance; you know that 'a streak' at some point is statistically probable but you can't help but thinking the next toss has to break the streak because for some reason in your head it's not right. That unwillingness to accept randomness, our need for a pattern, often clouds our judgement when making decisions.

Unrealistic Optimism

We have touched upon optimism bias in the past. Optimism truly is a double-edged sword. On one hand it is extremely important to be able to look past a bad moment and tell yourself that it will get better. Optimism is one of the great drivers of human progress. On the other hand, if you never take those rose-coloured glasses off, you will make mistakes and take risks that could have been avoided. When assessing the possible negative outcomes associated with risky behaviour we often think 'it won't happen to me.' This is a brain trick: We are often insensitive to the base rate.

Unrealistic optimism is a pervasive feature of human life; it characterizes most people in most social categories. When they overestimate their personal immunity from harm, people may fail to take sensible preventive steps. If people are running risks because of unrealistic optimism, they might be able to benefit from a nudge.

Loss Aversion

When they have to give something up, they are hurt more than they are pleased if they acquire the very same thing.

We are familiar with loss aversion in the context described above but Thaler and Sunstein take the concept a step further and explain how it plays a role in 'default choices.' Loss aversion can make us so fearful of making the wrong decision that we don't make any decision. This explains why so many people settle for default options.

The combination of loss aversion with mindless choosing implies that if an option is designated as the 'default,' it will attract a large market share. Default options thus act as powerful nudges. In many contexts defaults have some extra nudging power because consumers may feel, rightly or wrongly, that default options come with an implicit endorsement from the default setter, be it the employer, government, or TV scheduler.

Of course, this is not the only reason default options are so popular. "Anchoring," which we mentioned above, plays a role here. Our mind anchors immediately to the default option, especially in unfamiliar territory for us.

We also have the tendency towards inertia, given that mental effort is tantamount to physical effort – thinking hard requires physical resources. If we don't know the difference between two 401(k) plans and they both seem similar, why expend the mental effort to switch away from the default investment option? You may not have that thought consciously; it often happens as a "click, whirr."

State of Arousal

Our preferred definition requires recognizing that people's state of arousal varies over time. To simplify things we will consider just the two endpoints: hot and cold. When Sally is very hungry and appetizing aromas are emanating from the kitchen, we can say she is in a hot state. When Sally is thinking abstractly on Tuesday about the right number of cashews she should consume before dinner on Saturday, she is in a cold state. We will call something 'tempting' if we consume more of it when hot than when cold. None of this means that decisions made in a cold state are always better. For example, sometimes we have to be in a hot state to overcome our fears about trying new things. Sometimes dessert really is delicious, and we do best to go for it. Sometimes it is best to fall in love. But it is clear that when we are in a hot state, we can often get into a lot of trouble.

For most of us, however, self-control issues arise because we underestimate the effect of arousal. This is something the behavioral economist George Loewenstein (1996) calls the 'hot-cold empathy gap.' When in a cold state, we do not appreciate how much our desires

and our behavior reflects a certain naivete about the effects that context can have on choice.

The concept of arousal is analogous to mood. At the risk of stating the obvious, our mood can play a definitive role in our decision making. We all know it, but how many among us truly use that insight to make better decisions?

This is one reason we advocate decision journals when it comes to meaningful decisions (probably no need to log in your cashew calculations); a big part of tracking your decisions is your *mood* when you make them. A zillion contextual clues go into your state of arousal, but taking a quick pause to note which state you're in as you make a decision can make a difference over time.

Mood is also affected by chemicals. This one may be familiar to you coffee (or tea) addicts out there. Do you recall the last time you felt terrible or uncertain about a decision when you were tired, only to feel confident and spunky about the same topic after a cup of java? Or, how about alcohol? There's a reason it's called a "social lubricant" – our decision making changes when we've consumed enough of it.

Lastly, the connection between *sleep* and mood goes deep. Need we say more?

Peer Pressure

Peer pressure is another tricky nudge that can be both positive or negative. We can be nudged to make better decisions when we think that our peer group is doing the same. If we think our neighbors conserve more energy or recycle more, we start making a better effort to reduce our consumption and recycle. If we think the people around us are eating better and exercising more we tend to do the same. Information we get from peer groups can also help us make better decisions because of 'collaborative filtering'; the choices of our peer groups help us filter out and narrow down our choices. If your friends who share similar views and tastes as you recommend book X, then you may like it as well. (Google, Amazon and Netflix are built on this principle).

However, if we are all reading the same book because we constantly see people with it, but none of us actually like it, then we all lose. We run off the mountain with the other lemmings.

Social influences come in two basic categories. The first involves information. If many people do something or think something, their actions and their thoughts convey information about what might be best for you to do or think. The second involves peer pressure. If you care about what other people think about you (perhaps in the mistaken belief that they are paying some attention to what you are doing), then you might go along with the crowd to avoid their wrath or curry their favor.

An important problem here is 'pluralistic ignorance' – that is, ignorance, on the part of all or most, about what other people think. We may follow a practice or a tradition not because we like it, or even think it defensible, but merely because we think that most other people like it. Many social practices persist for this reason, and a small shock, or nudge, can dislodge them.

How do we beat social influence? It's very difficult, and not always desirable: If you are about to enter a building a lot of people are running away from, there's a better than good chance you should too. But this useful instinct leads us awry.

A simple algorithm, when you feel yourself acting out of social proof, is to ask yourself: Would I still do this if everyone else was not?

95. Nassim Taleb on the Notion of Alternative Histories

We see what's visible and available. Often this is nothing more than randomness and yet we wrap a narrative around it. The trader who is rich must know what he is doing. A good outcome means we made the right decisions, right? Not so quick. If we were wise we would not judge the quality of a decision on its outcome. There are alternative histories worth considering.

Writing in *Fooled by Randomness: The Hidden Role of Chance in Life and in the Markets*, Nassim Taleb hits on the notion of alternative histories.

Taleb argues that we should judge people by the costs of the alternative, that is if history played out in another way. These “substitute courses of events are called alternative histories.”

Taleb writes:

Clearly, the quality of a decision cannot be solely judged based on its outcome, but such a point seems to be voiced only by people who fail (those who succeed attribute their success to the quality of their decision).

[...]

One can illustrate the strange concept of alternative histories as follows. Imagine an eccentric (and bored) tycoon offering you \$ 10 million to play Russian roulette, i.e., to put a revolver containing one bullet in the six available chambers to your head and pull the trigger. Each realization would count as one history, for a total of six possible histories of equal probabilities. Five out of these six histories would lead to enrichment; one would lead to a statistic, that is, an obituary with an embarrassing (but certainly original) cause of death. The problem is that only one of the histories is observed in reality; and the winner of \$ 10 million would elicit the admiration and praise of some fatuous journalist (the very same ones who unconditionally admire the Forbes 500 billionaires). Like almost every executive I have encountered during an eighteen-year career on Wall Street (the role of such executives in my view being no more than a judge of results delivered in a random manner), the public observes the external signs of wealth without even having a glimpse at the source (we call such source the generator.) Consider the possibility that the Russian roulette winner would be used as a role model by his family, friends, and neighbors. While the remaining five histories are not observable, the wise and thoughtful person could easily make a guess as to their attributes. It requires some thoughtfulness and personal courage. In addition, in time, if the roulette-betting fool keeps playing the game, the bad histories will tend to catch up with him. Thus, if a twenty-five-year-old played Russian roulette, say, once a year, there would be a very slim possibility of his surviving until his fiftieth birthday— but, if there are enough players, say thousands of twenty-five-year-old players, we can expect to see a handful of (extremely rich) survivors (and a very large cemetery).

[...]

The reader can see my unusual notion of alternative accounting: \$ 10 million earned through Russian roulette does not have the same value as \$ 10 million earned through the diligent and artful practice of dentistry. They are the same, can buy the same goods, except that one's dependence on randomness is greater than the other.

Reality is different than roulette. Consider that in the example above, while the result is unknown you know the odds, most of life is dealing with uncertainty. Bullets are infrequent, “like a revolver that would have hundreds, even thousands, of chambers instead of six.” After a while you forget about the bullet. You can't see the chamber and we generally think of risk in terms of what is visible.

Interestingly this is the core of the black swan, which is really the induction problem. No amount of evidence can allow the inference that something is true whereas one

counterexample can refute a conclusion. This idea is also related to the “denigration of history,” where we think things that happen to others would not happen to us.

96. Choosing your Choice Architect(ure)

*“Nothing will ever be attempted
if all possible objections must first be overcome.”*

— Samuel Johnson

In the book Nudge by Richard Thaler and Cass Sunstein they coin the terms ‘*Choice Architecture*’ and ‘*Choice Architect*’. For them, if you have an ability to influence the choices other people make, you are a choice architect.

Considering the number of interactions we have everyday, it would be quite easy to argue that we are all *Choice Architects* at some point. But this also makes the inverse true; we are also wandering around someone else’s *Choice Architecture*.

Let’s take a look at a few of the principles of good choice architecture, so we can get a better idea of when someone is trying to nudge us.

This information can then be used/weighed when making decisions.

Defaults

Thaler and Sunstein start with a discussion on “defaults” that are commonly offered to us: *For reasons we have discussed, many people will take whatever option requires the least effort, or the path of least resistance. Recall the discussion of inertia, status quo bias, and the ‘yeah, whatever’ heuristic. All these forces imply that if, for a given choice, there is a default option — an option that will obtain if the chooser does nothing — then we can expect a large number of people to end up with that option, whether or not it is good for them. And as we have also stressed, these behavioral tendencies toward doing nothing will be reinforced if the default option comes with some implicit or explicit suggestion that it represents the normal or even the recommended course of action.*

When making decisions people will often take the option that requires the least effort or the path of least resistance. This makes sense: It’s not just a matter of laziness, we also only have so many hours in a day. Unless you feel particularly strongly about it, if putting little to no effort towards something leads you forward (or at least doesn’t noticeably kick you backwards) this is what you are likely to do. Loss aversion plays a role as well. If we feel like the consequences of making a poor choice are high, we will simply decide to do nothing.

Inertia is another reason: If the ship is currently sailing forward, it can often take a lot of time and effort just to slightly change course.

You have likely seen many examples of inertia at play in your work environment and this isn’t necessarily a bad thing.

Sometimes we need that ship to just steadily move forward. The important bit is to realize when this is factoring into your decisions, or more specifically, when this knowledge is being used to nudge you into making specific choices.

Let’s think about some of your monthly recurring bills. While you might not be *reading* that magazine or *going* to the gym, you’re still *paying* for the ability to use that good or service. If you weren’t being auto-renewed monthly, what is the chance that you would put the effort into renewing that subscription or membership? Much lower, right? Publishers and gym owners know this, and they know you don’t want to go through the hassle of cancelling either, so they make that difficult, too. (They understand well our tendency to want to travel the path of least resistance and avoid conflict.)

This is also where they will imply that the default option is the *recommended* course of action. It sounds like this:

“We’re sorry to hear you no longer want the magazine Mr. Smith. You know, more than half of the fortune 500 companies have a monthly subscription to magazine X, but we understand if it’s not something you’d like to do at the moment.”

or

"Mr. Smith we are sorry to hear that you want to cancel your membership at GymX. We understand if you can't make your health a priority at this point but we'd love to see you back sometime soon. We see this all the time, these days everyone is so busy. But I'm happy to say we are noticing a shift where people are starting to make time for themselves, especially in your demographic..."

(Just cancel them. You'll feel better. We promise.)

The Structure of Complex Choices

We live in a world of reviews. Product reviews, corporate reviews, movie reviews... When was the last time you bought a phone or a car before checking the reviews? When was the last time that you hired an employee without checking out their references?

Thaler and Sunstein call this Collaborative Filtering and explain it as follows:

You use the judgements of other people who share your tastes to filter through the vast number of books or movies available in order to increase the likelihood of picking one you like. Collaborative filtering is an effort to solve a problem of choice architecture. If you know what people like you tend to like, you might well be comfortable in selecting products you don't know, because people like you tend to like them. For many of us, collaborative filtering is making difficult choices easier.

While collaborative filtering does a great job of making difficult choices easier we have to remember that companies also know that you will use this tool and will try to manipulate it. We just have to look at the information critically, compare multiple sources and take some time to review the reviewers.

These techniques can be useful for decisions of a certain scale and complexity: when the alternatives are understood and in small enough numbers. However, once we reach a certain size we require additional tools to make the right decision.

One strategy to use is what Amos Tversky (1972) called 'elimination by aspects.' Someone using this strategy first decides what aspect is most important (say, commuting distance), establishes a cutoff level (say, no more than a thirty-minute commute), then eliminates all the alternatives that do not come up to this standard. The process is repeated, attribute by attribute (no more than \$1,500 per month; at least two bedrooms; dogs permitted), until either a choice is made or the set is narrowed down enough to switch over to a compensatory evaluation of the 'finalists.'"

This is a very useful tool if you have a good idea of which attributes are of most value to you.

When using these techniques, we have to be mindful of the fact that the companies trying to sell us goods have spent a lot of time and money figuring out what attributes are important to you as well.

For example, if you were to shop for an SUV you would notice that there are a specific number of variables they all seem to have in common now (engine options, towing options, seating options, storage options). They are trying to nudge you not to eliminate them from your list. This forces you to do the tertiary research or better yet, this forces you to walk into dealerships where they will try to inflate the importance of those attributes (which they do best).

They also try to call things new names as a means to differentiate themselves and get onto *your* list. What do you mean our competitors don't have FLEXfuel?

Incentives

Incentives are so ubiquitous in our lives that it's very easy to overlook them. Unfortunately, this can influence us to make poor decisions.

Thaler and Sunstein believe this is tied into how *salient* the incentive is.

The most important modification that must be made to a standard analysis of incentives is salience. Do the choosers actually notice the incentives they face? In free markets, the answer is usually yes, but in important cases the answer is no.

Consider the example of members of an urban family deciding whether to buy a car. Suppose their choices are to take taxis and public transportation or to spend ten thousand dollars to buy a used car, which they can park on the street in front of their home. The only salient costs of owning this car will be the weekly stops at the gas station, occasional repair bills, and a yearly insurance bill. The opportunity cost of the ten thousand dollars is likely to be neglected. (In other words, once they purchase the car, they tend to forget about the ten thousand dollars and stop treating it as money that could have been spent on something else.) In contrast, every time the family uses a taxi the cost will be in their face, with the meter clicking every few blocks. So behavioral analysis of the incentives of car ownership will predict that people will underweight the opportunity costs of car ownership, and possibly other less salient aspects such as depreciation, and may overweight the very salient costs of using a taxi.

The problems here are *relatable* and *easily solved*: If the family above had written down all the numbers related to either taxi, public transportation, or car ownership, it would have been a lot more difficult for them to undervalue the salient aspects of any of their choices. (At least if the highest value attribute is cost).

This isn't an exhaustive list of all the daily nudges we face but it's a good start and some important, translatable, themes emerge.

- Realize when you are wandering around someone's choice architecture.
- Do your homework
- Develop strategies to help you make decisions when you are being nudged.

97. Simple Rules for Business Strategy

The book Simple Rules by Donald Sull and Kathleen Eisenhardt has a very interesting chapter on strategy, which tries to answer the following question: How do you translate your broad objectives into a strategy that can provide guidelines for your employees from day to day?

It's the last bit there which is particularly important — getting everyone on the same page. Companies don't seem to have a problem creating broad objectives (which isn't really a strategy). Your company might not call them that, they might call them “mission statements” or simply “corporate goals.” They sound all well and good, but very little thought is given to how we will actually implement these lofty goals.

As Sull and Eisenhardt put it:

Developing a strategy and implementing it are often viewed as two distinct activities — first you come up with the perfect plan and then you worry about how to make it happen. This approach, common through it is, creates a disconnect between what a company is trying to accomplish and what employees do on a day-to-day basis.

The authors argue that companies can bridge this gap between strategic intent and actual implementation by following three steps:

1. Figure out what will move the needles.
2. Choose a bottleneck.
3. Craft the rules.

1. Moving the Needles

The authors use a dual needle metaphor to visualize corporate profits. They see it as two parallel needles: an upper needle which represents revenues and a lower needle which represents costs. The first critical step is to identify which actions will drive a wedge between the needles causing an increase in profits, a decrease in costs, and sustain this over time.

In other words, as simple as it sounds, we need *an actual set of steps* to get from figure a. to figure b.

Fig. a

Fig. b

What action will become the wedge that will move the needles?

The authors believe the best way to answer this is to sit down with your management team and ask them to work as a group to answer the following three questions:

1. Who will we target as customers?

2. What product or service will we offer?
3. How will we provide this product at a profit?

When you are trying to massage out these answers remember to use inversion as well. *Equally important are the choices on who not to serve and what not to offer.*

Steve Jobs once pointed out that Apple was defined as much by what it didn't do as by what it did.

2. Bottlenecks

Speaking of *inversion*, in order to complete our goal we must also figure out what's holding us back from moving the needles — the bottlenecks standing in our way.

When it comes to implementing a strategy of simple rules, pinpointing the precise decision or activity where rules will have the most impact is half the battle. We use the term bottleneck to describe a specific activity or decision that hinders a company from moving the needles.

You may be surprised at the amount of bottlenecks you come across, so you'll have to practice some "triage" of your issues, sorting what's important from what's *really* important. The authors believe that the best bottlenecks to focus your attention on share three characteristics:

1. They have a direct and significant impact on value creation.
2. They should represent recurrent decisions (as opposed to 'one off' choices).
3. They should be obstacles that arise when opportunities exceed available resources.

Once we've established what the bottlenecks *are*, it's time to craft the rules which will provide you a framework in which to remove them.

3. Craft the Rules

Developing rules from the top down is a big mistake. When leaders rely on their gut instincts, they overemphasize recent events, build in their personal biases, and ignore data that doesn't fit with their preconceived notions. It is much better to involve a team, typically ranging in size from four to eight members, and use a structured process to harness members' diverse insights and points of view. When drafting the dream team to develop simple rules, it is critical to include some of the people who will be using them on a day-to-day basis.

This probably seems like common sense but we're guessing you have worked at least one place where all information and new initiatives came from above, and much of it seemingly came out of nowhere because you weren't likely involved.

In these situations it's very hard to get buy-in from the employees — yet they are the ones doing the work, implementing the rules. So we need to think about their involvement from the beginning.

Having users make the rules confers several advantages. First, they are closest to the facts on the ground and best positioned to codify experience into usable rules. Because they will make decisions based on the rules, they can strike the right balance between guidance and discretion, avoiding rules that are overly vague or restrictive. User can also phrase the rules in language that resonates for them, rather than relying on business jargon. By actively participating in the process, users are more likely to buy into the final rules and therefore apply them in practice. Firsthand knowledge also makes it easier to explain the rules, and their underlying rationale, to colleagues who did not participate in the process.

It's important to note here that this is a process, a process in which you are never done — *there is no real finish line*. You must always plan to learn and to *iterate* as you learn —

keep changing the plan as new information comes in. Rigidity to a plan is not a virtue; learning and adapting are virtues.

There's nothing wrong with strategy. In fact, without a strategy, it's hard to figure out what to do; some strategy or another must guide your actions as an organization. But it's simply not enough: *Detailed execution, at the employee level, is what gets things done*. That's what the *Simple Rules* are all about.

Strategy, in our view, lives in the simple rules that guide an organization's most important activities. They allow employees to make on-the-spot decisions and seize unexpected opportunities without losing sight of the big picture.

The process you use to develop simple rules matters as much as the rules themselves. Involving a broad cross-section of employees, for example, injects more points of view into the discussion, produces a shared understanding of what matters for value creation, and increases buy-in to the simple rules. Investing the time up front to clarify what will move the needles dramatically increases the odds that simple rules will be applied where they can have the greatest impact.

97. Blog Posts, Book Reviews, and Abstracts: On Shallowness

We're quite glad that you read Farnam Street, and we hope we're always offering you a massive amount of value. (If not, email us and tell us what we can do more effectively.) But there's a message all of our readers should appreciate: Blog posts are not enough to generate the deep fluency you need to truly understand or get better at something. We offer a starting point, not an end point.

This goes just as well for book reviews, abstracts, cliff's notes, and a good deal of short-form journalism.

This is a hard message for some who want a shortcut. They want the "gist" and the "high level takeaways", without doing the work or eating any of the broccoli. They think that's all it takes: Check out a 5-minute read, and instantly their decision making and understanding of the world will improve right-quick. Most blogs, of course, encourage this kind of shallowness. Because it makes you feel that the whole thing is pretty easy.

Here's the problem: The world is more complex than that. It doesn't actually work this way. The nuanced detail behind every "high level takeaway" gives you the context needed to use it in the real world. The exceptions, the edge cases, and the contradictions.

Let me give you an example.

A high-level takeaway from reading Kahneman's Thinking Fast, and Slow would be that we are subject to something he and Amos Tversky call the Representativeness Heuristic. We create models of things in our head, and then fit our real-world experiences to the model, often over-fitting drastically. A very useful idea.

However, that's not enough. There are so many follow-up questions. Where do we make the most mistakes? Why does our mind create these models? Where is this generally useful? What are the nuanced examples of where this tendency fails us? And so on. Just knowing about the Heuristic, knowing that it exists, won't perform any work for you.

Or take the rise of human species as laid out by Yuval Harari. It's great to post on his theory; how myths laid the foundation for our success, how "natural" is probably a useless concept the way it's typically used, and how biology is the great enabler.

But Harari's book itself contains the relevant detail that fleshes all of this out. And further, his bibliography is full of resources that demand your attention to get even more backup. How did he develop that idea? You have to look to find out.

Why do all this? Because without the massive, relevant detail, your mind is built on a house of cards.

What Farnam Street and a lot of other great resources give you is something like a brief map of the territory.

Welcome to Colonial Williamsburg! Check out the re-enactors, the museum, and the theatre. Over there is the Revolutionary City. Gettysburg is 4 hours north. Washington D.C. is closer to 2.5 hours.

Great – now you have a lay of the land. Time to dig in and actually learn about the American Revolution. (This book is awesome, if you actually want to do that.)

Going back to Kahneman, one of his and Tversky's great findings was the concept of the Availability Heuristic. Basically, the mind operates on what it has close at hand.

As Kahneman puts it, "An essential design feature of the associative machine is that it represents only activated ideas. Information that is not retrieved (even unconsciously) from memory might as well not exist. System 1 excels at constructing the best possible story that incorporates ideas currently activated, but it does not (cannot) allow for information it does not have."

That means that in the moment of decision making, when you're thinking hard on some complex problem you face, it's unlikely that your mind is working all that successfully without the details. It doesn't have anything to draw on. It'd be like a chess player who

read a book about great chess players, but who hadn't actually studied all of their moves. Not very effective.

The great difficulty, of course, is that we lack the time to dig deep into everything. Opportunity costs and trade-offs are quite real.

That's why you must develop excellent filters. What's worth learning this deeply? We think it's the first-principle style mental models. The great ideas from physical systems, biological systems, and human systems. The new-new thing you're studying is probably either A. Wrong or B. Built on one of those great ideas anyways. Farnam Street, in a way, is just a giant filtering mechanism to get you started down the hill.

But don't stop there. Don't stop at the starting line. Resolve to increase your depth and stop thinking you can have it all in 5 minutes or less. Use our stuff, and whoever else's stuff you like, as an entrée to the real thing.

98. Creating a Decision Journal: Template And Example Included

We all make decisions. And yet few of us think about what we can learn from our past decisions to make smarter decisions in the future. A decision journal helps you learn from past decisions, think through current decisions, and avoid problems before they happen. In this article we'll cover:

- Your Product is Decisions
- What is a Decision Journal
- A Decision Journal Template
- An Example Decision
- Tips on Using a Decision Journal

Ok, let's dig in.

Your Product is Decisions

In most organizations your product is decisions. By and large, your success will be the sum of the decisions you make over your career. The problem is it's not easy to get better at making decisions.

Bosses would be the easy solution to helping you improve. After all, they have the best view of the problem and you. They should be able to point out strengths and weaknesses in your decision process as well as your judgment. All of this is known at the time you made the decision. This is hard and subjective and requires people doing a lot of thinking. So bosses tend to default to resulting, a process by which the outcome of the decision is attached to the process used to make that decision. Under resulting good outcomes are the product of good decisions and bad outcomes are the product of bad decisions. The problem isn't that people don't want to get better at decisions, it's the system that's preventing them from doing so.

Even if we can't get our boss to help us make better decisions we can take things into our own hands. The way to test the quality of your decisions is to test the process by which you make them. Daniel Kahneman, Nobel Prize winner and dean of biases, argues that using a decision journal is the best solution. Kahneman said:

Go down to a local drugstore and buy a very cheap notebook and start keeping track of your decisions. And the specific idea is whenever you're making a consequential decision, something going in or out of the portfolio, just take a moment to think, write down what you expect to happen, why you expect it to happen and then actually, and this is optional, but probably a great idea, is write down how you feel about the situation, both physically and even emotionally. Just, how do you feel? I feel tired. I feel good, or this stock is really draining me. Whatever you think.

The key to doing this is that it prevents something called hindsight bias, which is no matter what happens in the world, we tend to look back on our decision-making process, and we tilt it in a way that looks more favorable to us, right? So we have a bias to explain what has happened.

A decision journal helps you collect accurate and honest feedback on what you were thinking at the time you made the decision. This feedback helps you see when you were stupid and lucky as well as when you were smart and unlucky. Finally, you can get the feedback you need to make better decisions.

The key to understanding the limits to our knowledge (see circle of competence) is to check the results of our decisions against what we thought was going to happen and why we thought it was going to happen. That feedback loop is incredibly powerful because our minds won't provide it by themselves.

I'll give you the spoiler right now. We don't know as much as we think we know. We're fooled into thinking that we understand something when we don't and we have no means to correct ourselves.

Our minds revise history to preserve our view of ourselves. The story that we tell ourselves conflates the cause and effect of a decision we made and the actual outcome. The best cure for this revising is the decision journal.

What is a Decision Journal?

You can think of a decision journal as quality control for our thinking — something like what we'd find in a manufacturing plant or a restaurant. Using a decision journal is simple but not easy. Implementing one requires discipline and humility.

Not all decisions need to be journaled. Decisions of consequence should be logged with the basics of the situation, what you expect to happen, and why.

You should write in your decision journal before you make the decision official. Writing is the process where you realize that you don't know what you think you know. Writing about your decision forces you to explain your thinking. If we write about the decision after we make it, it's often too late to do anything about it.

Write your decision down sleep on it and read it with fresh eyes in the morning. Often you'll find that what you wrote doesn't make sense. Catching mistakes before you make a decision saves you time and money.

A Decision Journal Template

The key question is what information to include in your decision journal. Here's the template we use at FS.

Decision No: _____

Date: _____

Time: _____

Decision: _____

Mental/Physical State (check boxes)

Energized ☐ Focused ☐ Relaxed ☐

Confident ☐ Tired ☐ Accepting ☐

Accommodating ☐ Anxious ☐ Resigned ☐

Frustrated ☐ Angry ☐

The situation/context:

The problem statement or frame:

The variables that govern the situation include:

[Click for PDF](#)

Whenever you're making a consequential decision, either individually or as part of a group, you take a moment and write down:

1. The situation or context
2. The problem statement or frame
3. The variables that govern the situation
4. The complications or complexity as you see it
5. Alternatives that were seriously considered and why they were not chosen (think: the work required to have an opinion)
6. A paragraph explaining the range of outcomes
7. A paragraph explaining what you expect to happen and the reasoning and actual probabilities you assign to each projected outcome (The degree of confidence matters, a lot.)

8. The time of day you're making the decision and how you feel physically and mentally (If you're tired, for example, write it down.)

You have to make this part your own. I've seen others include:

- What's the primary thesis
- What is the expected outcome(s)
- What are the second and third-order consequences
- What is the worst-case scenario and why that's ok
- What is the potential upside beyond the core thesis
- What emotions am I experiencing
- What is the opportunity cost (by doing this what am I not doing)
- What unique advantages or insights do I have in this situation
- Who is the best person to make this decision
- What does this look like in 5 weeks, 5 months, 5 years?

An Example Decision

Perhaps an example will help illustrate. Here's a real decision that I made using the FS decision journal template.

Tips on Using a Decision Journal

Here are some tips to keep in mind as you implement your decision journal.

Your decision journal can be tailored to the situation and context. Specific decisions might include trade-offs, second-order effects, weighting criteria, or other relevant factors. These examples are only to get you started.

We can't improve our thinking if we can't see it. Don't spend too much time on the brief and obvious insights. Often our first thoughts represent the thinking of someone else and not our own thinking.

Any decision you're journaling is inherently complex and may involve non-linear systems. In such a world, small effects can cause disproportionate responses whereas bigger ones might have no impact. Remember that causality is complex, especially in complex domains.

Two common ways people wiggle out of their own decisions are hindsight bias and jargon. It's hard to remember what we knew at the time and what we were thinking. Hindsight makes things far more explainable and changes our story. A decision journal helps combat this by recording what you knew and what you thought at the time. When you look at your own handwriting you come face to face with the person you were when you made the decision. There is nowhere to hide.

The words we use are also important. When we use vague terms, we give ourselves wiggle room. If we want to get better at making decisions we can't give ourselves wiggle room. Be clear. Be direct. Be simple. An 8-year-old should understand what decision you're making and why.

A decision journal that sits on the shelf is less useful than one that gets reviewed. Every six months or so pick it up and look at your past decisions, update entries with what actually happened, and spend time thinking about your process.

Realizing where you make mistakes, how you make them, what types of decisions you're bad at, etc., helps you make better decisions going forward. When you start to identify patterns, you can change your decision process to help account for the things you miss. Just because you had a bad outcome doesn't mean you made a bad decision. You might have made the right decision (which, in our sense, means that used a good process) and still had a bad outcome. We call that a bad break.

When you use a decision journal, you'll discover two things right away. First, you're right a lot of the time. Second, it's often for the wrong reasons. Discovering how lucky you are can be somewhat humbling. This is where the learning begins.

99. Making Compassionate Decisions: The Role of Empathy in Decision Making

“The biggest deficit that we have in our society and in the world right now is an empathy deficit. We are in great need of people being able to stand in somebody else’s shoes and see the world through their eyes.”

— Barack Obama

You don’t have to look hard to find quotes expounding the need for more empathy in society. As with Barack Obama’s quote above, we are encouraged to actively build empathy with others — especially those who are different from us. The implicit message in these pleas is that empathy will make us treat each other with more respect and caring and will help reduce violence. But is this true? Does empathy make us appreciate others, help us behave in moral ways, or help us make better decisions?

These are questions Paul Bloom tackles in his book *Against Empathy: The Case for Rational Compassion*. As the title suggests, Bloom’s book makes a case against empathy as an inherent force for good and takes a closer look at what empathy is (and is not), how empathy works in our brains, how empathy can lead to immoral outcomes despite our best intentions, and how we can improve our ability to have a positive impact by strengthening our intelligence, compassion, self-control, and ability to reason.

To explore these questions, we first need to define what we’re talking about.

What Is Empathy?

Empathy is an often-used word that can mean different things. Bloom quotes one team of empathy researchers who joke that “there are probably nearly as many definitions of empathy as people working on this topic.” For his part, Bloom defines empathy as “the act of coming to experience the world as you think someone else does.” This type of empathy was explored by philosophers of the Scottish Enlightenment. Bloom writes:

As Adam Smith put it, we have the capacity to think about another person and “place ourselves in his situation and become in some measure the same person with him, and thence form some idea of his sensations, and even feel something which, though weaker in degree, is not altogether unlike them.”

This is the definition and view of empathy that Bloom devotes most of the book to exploring. This is the “standing in another man’s shoes” type of empathy from Barack Obama’s quote above, which Bloom calls *emotional empathy*.

[quote]“I feel your pain” is more than a metaphor. It’s literal.[/quote]

With emotional empathy, you actually experience a weaker degree of what somebody else feels. Researchers in recent years have been able to show that empathic responses of pain occur in the same area of the brain where real pain is experienced.

So “I feel your pain” isn’t just a gooey metaphor; it can be made neurologically literal: Other people’s pain really does activate the same brain area as your own pain, and more generally, there is neural evidence for a correspondence between self and other.

To make the shoe metaphor literal, imagine that you see somebody drop something heavy on their foot — you flinch because you know what this feels like and the parts of your brain that experience pain (the anterior insula and the cingulate cortex) react. You don’t feel the same degree of pain, of course — you didn’t drop anything on your foot after all — but it is likely that you have an involuntary physical reaction like a flinch, a facial grimace, or an audible outburst. This is an emotionally empathic response.

But there is another form of empathy that Bloom wants us to be aware of and consider differently. It relates to our ability to understand what is going on in the minds of others.

Bloom refers to this form as *cognitive empathy*:

... if I understand that you are in pain without feeling it myself, this is what psychologists describe as social cognition, social intelligence, mind reading, theory of mind, or mentalizing. It's also sometimes described as a form of empathy—"cognitive empathy" as opposed to "emotional empathy."

In this sense, cognitive empathy speaks to our capacity to understand what is going on in the minds of others. In the case of pain, which is where a lot of empathy research is done, we're not talking about feeling any degree of pain, as we might with emotional empathy, but instead, we simply understand that the other person is feeling pain without feeling it ourselves. Cognitive empathy goes beyond pain — our ability to understand what is going on in somebody else's mind is an important part of being human and is necessary for us to relate to each other.

[quote]Empathy and compassion are synonyms in many dictionaries and used interchangeably by many, but they have different characteristics.[/quote]

The brain is, of course, very complicated, so it is plausible that these two types of empathy could take place in the same part of the brain. So far, though, the research seems to indicate that they are largely separate:

In a review article, Jamil Zaki and Kevin Ochsner note that hundreds of studies now support a certain perspective on the mind, which they call "a tale of two systems." One system involves sharing the experience of others, what we've called empathy; the other involves inferences about the mental states of others—mentalizing or mind reading. While they can both be active at once, and often are, they occupy different parts of the brain. For instance, the medial prefrontal cortex, just behind the forehead, is involved in mentalizing, while the anterior cingulate cortex, sitting right behind that, is involved in empathy.

The difference between cognitive and emotional empathy is important for understanding Bloom's arguments. From Bloom's perspective, cognitive empathy is "...a useful and necessary tool for anyone who wishes to be a good person—but it is morally neutral." On the other hand, Bloom believes that emotional empathy is "morally corrosive," and the bulk of his attack is directed at highlighting the pitfalls of relying on emotional empathy while making the case for cultivating and practicing "rational compassion" instead.

I believe that the capacity for emotional empathy, described as "sympathy" by philosophers such as Adam Smith and David Hume, often simply known as "empathy" and defended by so many scholars, theologians, educators, and politicians, is actually morally corrosive. If you are struggling with a moral decision and find yourself trying to feel someone else's pain or pleasure, you should stop. This empathic engagement might give you some satisfaction, but it's not how to improve things and can lead to bad decisions and bad outcomes. Much better to use reason and cost-benefit analysis, drawing on a more distanced compassion and kindness.

Here again, the definition of the terms is important for understanding the argument. Empathy and compassion are synonyms in many dictionaries and used interchangeably by many, but they have different characteristics. Bloom outlines the difference:

... compassion and concern are more diffuse than empathy. It is weird to talk about having empathy for the millions of victims of malaria, say, but perfectly normal to say that you are concerned about them or feel compassion for them. Also, compassion and concern don't require mirroring of others' feelings. If someone works to help the victims of torture and does so with energy and good cheer, it doesn't seem right to say that as they do this, they are empathizing with the individuals they are helping. Better to say that they feel compassion for them.

Bloom references a review paper written by Tania Singer and Olga Klimecki to help make the distinction clear. Singer and Klimecki write:

In contrast to empathy, compassion does not mean sharing the suffering of the other: rather, it is characterized by feelings of warmth, concern and care for the other, as well as

a strong motivation to improve the other's well-being. Compassion is feeling for and not feeling with the other.

To summarize, emotional empathy could be simply described as “feeling what others feel,” cognitive empathy as “understanding what others feel,” and compassion as “caring about how others feel.”

[quote]Emotional empathy could be simply described as “feeling what others feel,” cognitive empathy as “understanding what others feel,” and compassion as “caring about how others feel.”[/quote]

Empathy and Morality

Many people believe that our ability to empathize is the basis for morality because it causes us to consider our actions from another's perspective. “Treat others as you would like to be treated” is the basic morality lesson repeated thousands of times to children all over the world.

In this way, empathy can lead us to rely on our self-centered nature. If this is true, Bloom suggests that the argument in its simplest form would go like this:

Everyone is naturally interested in him- or herself; we care most about our own pleasure and pain. It requires nothing special to yank one's hand away from a flame or to reach for a glass of water when thirsty. But empathy makes the experiences of others salient and important—your pain becomes my pain, your thirst becomes my thirst, and so I rescue you from the fire or give you something to drink. Empathy guides us to treat others as we treat ourselves and hence expands our selfish concerns to encompass others.

In this way, the willful exercise of empathy can motivate kindness that would never have otherwise occurred. Empathy can make us care about a slave, or a homeless person, or someone in solitary confinement. It can put us into the mind of a gay teenager bullied by his peers, or a victim of rape. We can empathize with a member of a despised minority or someone suffering from religious persecution in a faraway land. All these experiences are alien to me, but through the exercise of empathy, I can, in some limited way, experience them myself, and this makes me a better person.

When we consider the plight of others by imagining ourselves in their situation, we experience an empathic response that can cause us to evaluate the morality of our actions.

[quote]When we consider the plight of others by imagining ourselves in their situation, we experience an empathic response that can cause us to evaluate the morality of our actions.[/quote]

In an interview, Steven Pinker hypothesizes that it was an increase in empathy, made possible by the technology of the printing press and the resulting increase in literacy, that led to the Humanitarian Revolution during the Enlightenment. The increase in empathy brought about by our ability to read accounts of violent punishments like disembowelment and mutilation caused us to reconsider the morality of treating other human beings in such ways.

So in certain instances, empathy can play a role in motivating us to take moral action. But is an empathic response required to do so?

To use a classic example from philosophy—first thought up by the Chinese philosopher Mencius—imagine that you are walking by a lake and see a young child struggling in shallow water. If you can easily wade into the water and save her, you should do it. It would be wrong to keep walking.

What motivates this good act? It is possible, I suppose, that you might imagine what it feels like to be drowning, or anticipate what it would be like to be the child's mother or father hearing that she drowned. Such empathic feelings could then motivate you to act. But that is hardly necessary. You don't need empathy to realize that it's wrong to let a child drown. Any normal person would just wade in and scoop up the child, without bothering with any of this empathic hoo-ha.

And so there has to be more to morality than empathy. Our decisions about what's right and what's wrong, and our motivations to act, have many sources. One's morality can be rooted in a religious worldview or a philosophical one. It can be motivated by a more diffuse concern for the fates of others—something often described as concern or compassion...

I hope most people reading this would agree that failing to attempt to save a drowning child or supporting or perpetrating violent punishments like disembowelment would be at the very least morally reprehensible, if not outright evil.

But what motivates people to be “evil”? For researchers like Simon Baron-Cohen, evil is defined as “empathy erosion” — truly evil people lack the capacity to empathize, and it is this lack of empathy that causes them to act in evil ways. Bloom looks at the question of what causes people to be evil from a slightly different angle:

Indeed, some argue that the myth of pure evil gets things backward. That is, it's not that certain cruel actions are committed because the perpetrators are self-consciously and deliberately evil. Rather it is because they think they are doing good. They are fueled by a strong moral sense.

When the perpetrators of violence or cruelty believe that their actions are morally justified, what motivates them? Bloom suggests that it can be empathy. Empathy often causes us to choose sides, to choose whom to empathize with. We see this tendency play out in politics all the time.

[quote]Empathy often causes us to choose sides, to choose whom to empathize with.[/quote]

Politicians representing one side believe they are saving the world, while representatives on the other side believe that their adversaries are out to destroy civilization as we know it. If I believe that I am protecting a person or group of people whom I choose to empathize with, then I may be motivated to act in a way I believe is morally justified, even though others may believe that I have harmed them.

Steven Pinker weighed in on this issue when he wrote the following in *The Better Angels of our Nature*:

If you added up all the homicides committed in pursuit of self-help justice, the casualties of religious and revolutionary wars, the people executed for victimless crimes and misdemeanors, and the targets of ideological genocides, they would surely outnumber the fatalities from amoral predation and conquest.

Bloom quotes Pinker and goes on to write:

Henry Adams put this in stronger terms, with regard to Robert E. Lee: “It's always the good men who do the most harm in the world.”

This might seem perverse. How can good lead to evil? One thing to keep in mind here is that we are interested in beliefs and motivations, not what's good in some objective sense. So the idea isn't that evil is good; rather, it's that evil is done by those who think they are doing good.

So from a moral perspective, empathy can lead us astray. We may believe we are doing good or that our actions are justified but this may not necessarily be true for all involved. This is especially troublesome when we consider how we are affected by a growing list of cognitive biases.

Empathy and Biases

While empathy may not be required to motivate us to save a drowning child, it can still help us consider the differing experiences or suffering of another person thus motivating us to consider things from their perspective or thus act to relieve their suffering:

I see the bullied teenager and might be tempted initially to join in with his tormenters, out of sadism or boredom or a desire to dominate or be popular, but then I empathize—I feel his pain, I feel what it's like to be bullied—so I don't add to his suffering. Maybe I even rise to his defense. Empathy is like a spotlight directing attention and aid to where it's needed.

On the surface this seems like an excellent case for the positive power of empathy; it shines a “spotlight” on a person in need and motivates us to help them. But what happens when we dig a little deeper into this metaphor? Bloom writes

... spotlights have a narrow focus, and this is one problem with empathy. It does poorly in a world where there are many people in need and where the effects of one's actions are diffuse, often delayed, and difficult to compute, a world in which an act that helps one person in the here and now can lead to greater suffering in the future.

He adds:

Further, spotlights only illuminate what they are pointed at, so empathy reflects our biases. Although we might intellectually believe that the suffering of our neighbor is just as awful as the suffering of someone living in another country, it's far easier to empathize with those who are close to us, those who are similar to us, and those we see as more attractive or vulnerable and less scary. Intellectually, a white American might believe that a black person matters just as much as a white person, but he or she will typically find it a lot easier to empathize with the plight of the latter than the former. In this regard, empathy distorts our moral judgments in pretty much the same way that prejudice does.

We are all predisposed to care more deeply for those we are close to. From a purely biological perspective, we will care for and protect our children and families before the children or families of strangers. Our decision making often falls victim to narrow framing, and our actions are affected by biases like Liking/Loving and Disliking/Hating and our tendency to discount the pain of people we don't like:

We are constituted to favor our friends and family over strangers, to care more about members of our own group than people from different, perhaps opposing, groups. This fact about human nature is inevitable given our evolutionary history. Any creature that didn't have special sentiments toward those that shared its genes and helped it in the past would get its ass kicked from a Darwinian perspective; it would falter relative to competitors with more parochial natures. This bias to favor those close to us is general—it influences who we readily empathize with, but it also influences who we like, who we tend to care for, who we will affiliate with, who we will punish, and so on.

There are many causes for human biases — empathy is only one — but taking a step back, we can see how the intuitive gut responses motivated by emotional empathy can negatively affect our ability to make rational decisions.

Empathy's narrow focus, specificity, and innumeracy mean that it's always going to be influenced by what captures our attention, by racial preferences, and so on. It's only when we escape from empathy and rely instead on the application of rules and principles or a calculation of costs and benefits that we can, to at least some extent, become fair and impartial.

While many of us are motivated to be good and to make good decisions, it isn't always cut and dry. Our preferences for whom to help or which organizations to support are affected by our biases. If we're not careful, empathy can affect our ability to see the potential impacts of our actions. However, considering these impacts takes much more than empathy and a desire to do good; it takes awareness of our biases and mental effort to combat their effects:

... doing actual good, instead of doing what feels good, requires dealing with complex issues and being mindful of exploitation from competing, sometimes malicious and greedy, interests. To do so, you need to step back and not fall into empathy traps. The conclusion is not that one shouldn't give, but rather that one should give intelligently, with an eye toward consequences.

In addition to biases like Liking/Loving and Disliking/Hating, empathy can lead to biases related to the Representative Heuristic. Actions motivated by empathy often fail to take the broader picture into account; the spotlight doesn't encourage us to consider base rates or

sample size when we make our decisions. Instead, we are motivated by positive emotions for a specific individual or small group:

Empathy is limited as well in that it focuses on specific individuals. Its spotlight nature renders it innumerate and myopic: It doesn't resonate properly to the effects of our actions on groups of people, and it is insensitive to statistical data and estimated costs and benefits.

Part of the challenge that exists with empathy is this innumeracy that Bloom describes. It is impossible for us to form genuine empathic connections with abstractions. Conversely, if we see the suffering of one, empathy can motivate us to help make it stop. As Mother Theresa said, "If I look at the mass, I will never act. If I look at the one, I will." This is what psychologists call "the identifiable victim effect."

[quote]While many of us are motivated to be good and to make good decisions, it isn't always cut and dry.[/quote]

Perhaps an example will help illustrate. On October 17, 1987, 18-month-old Jessica McClure fell 22 feet down an eight-inch-diameter well in the backyard of her home in Midland, Texas. Over the next 2 ½ days, fire, police, and volunteer rescuers worked around the clock to save her. Media coverage of the emergency was broadcast all over the world resulting in Jessica McClure becoming internationally known as "Baby Jessica" and prompting then-President Ronald Reagan to proclaim that "...everybody in America became the godmothers and godfathers of Jessica while this was going on." The intense coverage and global awareness led to an influx of donations, resulting in an \$800,000 trust being established in Jessica's name.

What prompted this massive outpouring of concern and support? There are millions of children in need every day all over the world. How many of the people who sent donations to Baby Jessica had ever tried to help these faceless children? In the case of Baby Jessica, they had an identifiable victim, and empathy motivated many of them to help Jessica and her family. They could imagine what it might feel like for those poor parents and they felt genuine concern for the child's future; all the other needy children around the world were statistical abstractions. This ability to identify and put a face on the suffering child and their family enables us to experience an empathic response with them, but the random children and their families remain empathically out of reach.

None of this is to say that rescuers should not have worked to save Jessica McClure — she was a real-world example of Mencius's proverbial drowning child — but there are situations every day where we choose to help individuals at the cost of the continued suffering of others. Our actions often have diffuse and unknowable impacts.

If our concern is driven by thoughts of the suffering of specific individuals, then it sets up a perverse situation in which the suffering of one can matter more than the suffering of a thousand.

Furthermore, not only are we more likely to empathize with the identifiable victim, our empathy has its limits in scale as well. If we hear that an individual in a faraway land is suffering, we may have an empathic response, but will that response be increased proportionally if we learned that thousands or millions of people suffered? Adam Smith got to the heart of this question in The Theory of Moral Sentiments when he wrote:

Let us suppose that the great empire of China, with all its myriads of inhabitants, was suddenly swallowed up by an earthquake, and let us consider how a man of humanity in Europe, who had no sort of connection with that part of the world, would be affected upon receiving intelligence of this dreadful calamity. He would, I imagine, first of all, express very strongly his sorrow for the misfortune of that unhappy people, he would make many melancholy reflections upon the precariousness of human life, and the vanity of all the labors of man, which could thus be annihilated in a moment. He would too, perhaps, if he was a man of speculation, enter into many reasonings concerning the effects which this disaster might produce upon the commerce of Europe, and the trade and business of the

world in general. And when all this fine philosophy was over, when all these humane sentiments had been once fairly expressed, he would pursue his business or his pleasure, take his repose or his diversion, with the same ease and tranquility, as if no such accident had happened.

Empathy can inadvertently motivate us to act to save the one at the expense of the many. While the examples provided are by no means clear-cut issues, it is worth considering how the morality or goodness of our actions to help the few may have negative consequences for the many.

Charlie Munger has written and spoken about the Kantian Fairness Tendency, in which he suggests that for certain systems to be moral to the many, they must be unfair to the few. [quote]For certain systems to be moral to the many, they must be unfair to the few.[/quote] Empathy and Reason

We are emotional creatures, then, but we are also rational beings, with the capacity for rational decision-making. We can override, deflect, and overrule our passions, and we often should do so. It's not hard to see this for feelings like anger and hate—it's clear that these can lead us astray, that we do better when they don't rule us and when we are capable of circumventing them.

While we need kindness and compassion and we should strive to be good people making good decisions, we are not necessarily well served by empathy in this regard; emotional empathy's negatives often outweigh its positives. Instead, we should rely on our capacity to reason and control our emotions. Empathy is not something that can be removed or ignored; it is a normal function of our brains after all, but we can and do combine reason with our natural instincts and intuitions:

The idea that human nature has two opposing facets—emotion versus reason, gut feelings versus careful, rational deliberation—is the oldest and most resilient psychological theory of all. It was there in Plato, and it is now the core of the textbook account of cognitive processes, which assumes a dichotomy between “hot” and “cold” mental processes, between an intuitive “System 1” and a deliberative “System 2.”

We know from Daniel Kahneman's Thinking, Fast and Slow that these two systems are not inherently separate in practice. They are both functioning in our brains at the same time. Some decisions are made faster due to heuristics and intuitions from experiences or our biology, while other decisions are made in a more deliberative and slow fashion using reason. Bloom writes:

We go through a mental process that is typically called “choice,” where we think about the consequences of our actions. There is nothing magical about this. The neural basis of mental life is fully compatible with the existence of conscious deliberation and rational thought—with neural systems that analyze different options, construct logical chains of argument, reason through examples and analogies, and respond to the anticipated consequences of actions.

We have an impulsive, emotional, and intuitive decision-making system in System 1 and a deliberative, reasoning, and (sometimes) rational decision-making system in System 2. [quote]We will always have emotional reactions, but on average our decision making will be better served by improving our ability to reason rather than leveraging our ability to empathize[/quote]

We will always have emotional reactions, but on average our decision making will be better served by improving our ability to reason rather than by leveraging our ability to empathize. One way to increase our ability to reason is to focus on improving our self-control:

Self-control can be seen as the purest embodiment of rationality in that it reflects the working of a brain system (embedded in the frontal lobe, the part of the brain that lies behind the forehead) that restrains our impulsive, irrational, or emotive desires.

While Bloom is unabashedly against empathy as an inherent force for good in the world, he is also a firm supporter of being and doing good. He believes that the “feeling with” nature of emotional empathy leads us to make biased and bad decisions despite our best intentions and that we should instead foster and encourage the “caring for” nature of compassion while combining it with our intelligence, self-control, and ability to reason: *... none of this is to deny the importance of traits such as compassion and kindness. We want to nurture these traits in our children and work to establish a culture that prizes and rewards them. But they are not enough. To make the world a better place, we would also want to bless people with more smarts and more self-control. These are central to leading a successful and happy life—and a good and moral one.*

100. OODA LOOP: What You Can Learn from Fighter Pilots About Making Fast and Accurate Decisions

“What is strategy? A mental tapestry of changing intentions for harmonizing and focusing our efforts as a basis for realizing some aim or purpose in an unfolding and often unforeseen world of many bewildering events and many contending interests.”

— John Boyd

What techniques do people use in the most extreme situations to make decisions? What can we learn from them to help us make more rational and quick decisions?

If these techniques work in the most drastic scenarios, they have a good chance of working for us. This is why military mental models can have such wide, useful applications outside their original context.

Military mental models are constantly tested in the laboratory of conflict. If they weren't agile, versatile, and effective, they would quickly be replaced by others. Military leaders and strategists invest a great deal of time in developing and teaching decision-making processes.

One strategy that I've found repeatedly effective is the OODA loop.

Developed by strategist and U.S. Air Force Colonel John Boyd, the OODA loop is a practical concept designed to be the foundation of rational thinking in confusing or chaotic situations. OODA stands for Observe, Orient, Decide, and Act.

Boyd developed the strategy for fighter pilots. However, like all good mental models, it can be extended into other fields. We used it at the intelligence agency I used to work at. I know lawyers, police officers, doctors, businesspeople, politicians, athletes, and coaches who use it.

Fighter pilots have to work fast. Taking a second too long to make a decision can cost them their lives. As anyone who has ever watched *Top Gun* knows, pilots have a lot of decisions and processes to juggle when they're in dogfights (close-range aerial battles). Pilots move at high speeds and need to avoid enemies while tracking them and keeping a contextual knowledge of objectives, terrains, fuel, and other key variables.

Dogfights are nasty. I've talked to pilots who've been in them. They want the fights to be over as quickly as possible. The longer they go, the higher the chances that something goes wrong. Pilots need to rely on their creativity and decision-making abilities to survive. There is no game plan to follow, no schedule or to-do list. There is only the present moment when everything hangs in the balance.

Forty-Second Boyd

Boyd was no armchair strategist. He developed his ideas during his own time as a fighter pilot. He earned the nickname “Forty-Second Boyd” for his ability to win any fight in under 40 seconds.

In a tribute written after Boyd's death, General C.C. Krulak described him as “a towering intellect who made unsurpassed contributions to the American art of war. Indeed, he was one of the central architects of the reform of military thought.... From John Boyd we learned about competitive decision making on the battlefield—compressing time, using time as an ally.”

Reflecting Robert Greene's maxim that everything is material, Boyd spent his career observing people and organizations. How do they adapt to changeable environments in conflicts, business, and other situations?

Over time, he deduced that these situations are characterized by uncertainty. Dogmatic, rigid theories are unsuitable for chaotic situations. Rather than trying to rise through the military ranks, Boyd focused on using his position as colonel to compose a theory of the universal logic of war.

Boyd was known to ask his mentees the poignant question, “Do you want to be someone, or do you want to do something?” In his own life, he certainly focused on the latter path and, as a result, left us ideas with tangible value. The OODA loop is just one of many.

The Four Parts of the OODA Loop

Let’s break down the four parts of the OODA loop and see how they fit together.

OODA stands for Observe, Orient, Decide, Act. The description of it as a loop is crucial.

Boyd intended the four steps to be repeated again and again until a conflict finishes.

Although most depictions of the OODA loop portray it as a superficial idea, there is a lot of depth to it. Using it should be simple, but it has a rich basis in interdisciplinary knowledge.

1: Observe

The first step in the OODA Loop is to observe. At this stage, the main focus is to build a comprehensive picture of the situation with as much accuracy as possible.

A fighter pilot needs to consider: What is immediately affecting me? What is affecting my opponent? What could affect us later on? Can I make any predictions, and how accurate were my prior ones? A pilot’s environment changes rapidly, so these observations need to be broad and fluid.

And information alone is not enough. The observation stage requires awareness of the overarching meaning of the information. It also necessitates separating the information which is relevant for a particular decision from that which is not. You have to add context to the variables.

The observation stage is vital in decision-making processes.

For example, faced with a patient in an emergency ward, a doctor needs to start by gathering as much foundational knowledge as possible. That might be the patient’s blood pressure, pulse, age, underlying health conditions, and reason for admission. At the same time, the doctor needs to discard irrelevant information and figure out which facts are relevant for this precise situation. Only by putting the pieces together can she make a fast decision about the best way to treat the patient. The more experienced a doctor is, the more factors she is able to take into account, including subtle ones, such as a patient’s speech patterns, his body language, and the absence (rather than presence) of certain signs.

2: Orient

Orientation, the second stage of the OODA loop, is frequently misunderstood or skipped because it is less intuitive than the other stages. Boyd referred to it as the *schwerpunkt*, a German term which loosely translates to “the main emphasis.” In this context, to orient is to recognize the barriers that might interfere with the other parts of the process.

Without an awareness of these barriers, the subsequent decision cannot be a fully rational one. Orienting is all about connecting with reality, not with a false version of events filtered through the lens of cognitive biases and shortcuts.

“Orientation isn’t just a state you’re in; it’s a process. You’re always orienting.”

— John Boyd

Including this step, rather than jumping straight to making a decision, gives us an edge over the competition. Even if we are at a disadvantage to begin with, having fewer resources or less information, Boyd maintained that the Orient step ensures that we can outsmart an opponent.

For Western nations, cyber-crime is a huge threat — mostly because for the first time ever, they can’t outsmart, outspend, or out-resource the competition. Boyd has some lessons for them.

Boyd believed that four main barriers prevent us from seeing information in an unbiased manner:

1. Our cultural traditions

2. Our genetic heritage
3. Our ability to analyze and synthesize
4. The influx of new information — it is hard to make sense of observations when the situation keeps changing

Boyd was one of the first people to discuss the importance of building a toolbox of mental models, prior to Charlie Munger's popularization of the concept among investors.

Boyd believed in “destructive deduction” — taking note of incorrect assumptions and biases and then replacing them with fundamental, versatile mental models. Only then can we begin to garner a reality-oriented picture of the situation, which will inform subsequent decisions.

Boyd employed a brilliant metaphor for this — a snowmobile. In one talk, he described how a snowmobile comprises elements of different devices. The caterpillar treads of a tank, skis, the outboard motor of a boat, the handlebars of a bike — each of those elements is useless alone, but combining them creates a functional vehicle.

As Boyd put it: “A loser is someone (individual or group) who cannot build snowmobiles when facing uncertainty and unpredictable change; whereas a winner is someone (individual or group) who can build snowmobiles, and employ them in an appropriate fashion, when facing uncertainty and unpredictable change.”

To orient ourselves, we have to build a metaphorical snowmobile by combining practical concepts from different disciplines.

Although Boyd is regarded as a military strategist, he didn't confine himself to any particular discipline. His theories encompass ideas drawn from various disciplines, including mathematical logic, biology, psychology, thermodynamics, game theory, anthropology, and physics. Boyd described his approach as a “scheme of pulling things apart (analysis) and putting them back together (synthesis) in new combinations to find how apparently unrelated ideas and actions can be related to one another.”

3. Decide

No surprises here. Having gathered information and oriented ourselves, we have to make an informed decision. The previous two steps should have generated a plethora of ideas, so this is the point where we choose the most relevant option.

Boyd cautioned against first-conclusion bias, explaining that we cannot keep making the same decision again and again. This part of the loop needs to be flexible and open to Bayesian updating. In some of his notes, Boyd described this step as the hypothesis stage. The implication is that we should test the decisions we make at this point in the loop, spotting their flaws and including any issues in future observation stages.

4. Act

While technically a decision-making process, the OODA loop is all about action. The ability to act upon rational decisions is a serious advantage.

The other steps are mere precursors. A decision made, now is the time to act upon it. Also known as the test stage, this is when we experiment to see how good our decision was. Did we observe the right information? Did we use the best possible mental models? Did we get swayed by biases and other barriers? Can we disprove the prior hypothesis? Whatever the outcome, we then cycle back to the first part of the loop and begin observing again.

Why the OODA Loop Works

The OODA loop has four key benefits.

1. Speed

Fighter pilots must make many decisions in fast succession. They don't have time to list pros and cons or to consider every available avenue. Once the OODA loop becomes part of their mental toolboxes, they should be able to cycle through it in a matter of seconds. Speed is a crucial element of military decision making. Using the OODA loop in everyday life, we probably have a little more time than a fighter pilot would. But Boyd emphasized the value of being decisive, taking initiative, and staying autonomous. These are universal assets and apply to many situations.

Take the example of modern growth hacker marketing.

"The ability to operate at a faster tempo or rhythm than an adversary enables one to fold the adversary back inside himself so that he can neither appreciate nor keep up with what is going on. He will become disoriented and confused..."

— John Boyd

The key advantage growth hackers have over traditional marketers is speed. They observe (look at analytics, survey customers, perform a/b tests, etc.) and orient themselves (consider vanity versus meaningful metrics, assess interpretations, and ground themselves in the reality of a market) before making a decision and then acting. The final step serves to test their ideas and they have the agility to switch tactics if the desired outcome is not achieved.

Meanwhile, traditional marketers are often trapped in lengthy campaigns which do not offer much in the way of useful metrics. Growth hackers can adapt and change their techniques every single day depending on what works. They are not confined by stagnant ideas about what worked before.

So, although they may have a small budget and fewer people to assist them, their speed gives them an advantage. Just as Boyd could defeat any opponent in under 40 seconds (even starting at a position of disadvantage), growth hackers can grow companies and sell products at extraordinary rates, starting from scratch.

2. Comfort With Uncertainty

Uncertainty does not always equate to risk. A fighter pilot is in a precarious situation, where there will be gaps in their knowledge. They cannot read the mind of the opponent and might have incomplete information about the weather conditions and surrounding environment. They can, however, take into account key factors such as the opponent's nationality, the type of airplane they are flying, and what their maneuvers reveal about their intentions and level of training.

If the opponent uses an unexpected strategy, is equipped with a new type of weapon or airplane, or behaves in an irrational, ideologically motivated way, the pilot must accept the accompanying uncertainty. However, Boyd belabored the point that uncertainty is irrelevant if we have the right filters in place.

If we don't, we can end up stuck at the observation stage, unable to decide or act. But if we do have the right filters, we can factor uncertainty into the observation stage. We can leave a margin of error. We can recognize the elements which are within our control and those which are not.

Three key principles supported Boyd's ideas. In his presentations, he referred to Gödel's Proof, Heisenberg's Uncertainty Principle, and the Second Law of Thermodynamics. Gödel's theorems indicate that any mental model we have of reality will omit certain information and that Bayesian updating must be used to bring it in line with reality. Our understanding of science illustrates this.

In the past, people's conception of reality missed crucial concepts such as criticality, relativity, the laws of thermodynamics, and gravity. As we have discovered these concepts, we have updated our view of the world. Yet we would be foolish to think that we now know everything and our worldview is complete. Other key principles remain undiscovered. The

same goes for fighter pilots — their understanding of what is going on during a battle will always have gaps. Identifying this fundamental uncertainty gives it less power over us. The second concept Boyd referred to is Heisenberg's Uncertainty Principle. In its simplest form, this principle describes the limit of the precision with which pairs of physical properties can be understood. We cannot know the position and the velocity of a body at the same time. We can know either its location or its speed, but not both. Although Heisenberg's Uncertainty Principle was initially used to describe particles, Boyd's ability to combine disciplines led him to apply it to planes. If a pilot focuses too hard on where an enemy plane is, they will lose track of where it is going and vice versa. Trying harder to track the two variables will actually lead to more inaccuracy! Heisenberg's Uncertainty Principle applies to myriad areas where excessive observation proves detrimental. Reality is imprecise.

Finally, Boyd made use of the Second Law of Thermodynamics. In a closed system, entropy always increases and everything moves towards chaos. Energy spreads out and becomes disorganized.

Although Boyd's notes do not specify the exact applications, his inference appears to be that a fighter pilot must be an open system or they will fail. They must draw "energy" (information) from outside themselves or the situation will become chaotic. They should also aim to cut their opponent off, forcing them to become a closed system. Drawing on his studies, Boyd developed his Energy Maneuverability theory, which recast maneuvers in terms of the energy they used.

"Let your plans be dark and impenetrable as night, and when you move, fall like a thunderbolt."

— Sun Tzu

3. Unpredictability

Using the OODA loop should enable us to act faster than an opponent, thereby seeming unpredictable. While they are still deciding what to do, we have already acted. This resets their own loop, moving them back to the observation stage. Keep doing this, and they are either rendered immobile or forced to act without making a considered decision. So, they start making mistakes, which can be exploited.

Boyd recommended making unpredictable changes in speed and direction, and wrote, "we should operate at a faster tempo than our adversaries or inside our adversaries['] time scales. ... Such activity will make us appear ambiguous (non predictable) [and] thereby generate confusion and disorder among our adversaries." He even helped design planes better equipped to make those unpredictable changes.

For the same reason that you can't run the same play 70 times in a football game, rigid military strategies often become useless after a few uses, or even one iteration, as opponents learn to recognize and counter them. The OODA loop can be endlessly used because it is a formless strategy, unconnected to any particular maneuvers.

We know that Boyd was influenced by Sun Tzu (he owned seven thoroughly annotated copies of *The Art of War*), and he drew many ideas from the ancient strategist. Sun Tzu depicts war as a game of deception where the best strategy is that which an opponent cannot pre-empt. Apple has long used this strategy as a key part of their product launches. Meticulously planned, their launches are shrouded in secrecy and the goal is for no one outside the company to see a product prior to the release.

When information has been leaked, the company has taken serious legal action as well as firing associated employees. We are never sure what Apple will put out next (just search for "Apple product launch 2017" and you will see endless speculation based on few facts). As a consequence, Apple can stay ahead of their rivals.

Once a product launches, rival companies scramble to emulate it. But by the time their technology is ready for release, Apple is on to the next thing and has taken most of the market share. Although inexpensive compared to the drawn-out product launches other companies use, Apple's unpredictability makes us pay attention. Stock prices rise the day after, tickets to launches sell out in seconds, and the media reports launches as if they were news events, not marketing events.

4. Testing

A notable omission in Boyd's work is any sort of specific instructions for how to act or which decisions to make. This is presumably due to his respect for testing. He believed that ideas should be tested and then, if necessary, discarded.

"We can't just look at our own personal experiences or use the same mental recipes over and over again; we've got to look at other disciplines and activities and relate or connect them to what we know from our experiences and the strategic world we live in."

— John Boyd

Boyd's OODA is a feedback loop, with the outcome of actions leading back to observations. Even in *Aerial Attack Study*, his comprehensive manual of maneuvers, Boyd did not describe any particular one as superior. He encouraged pilots to have the widest repertoire possible so they could select the best option in response to the maneuvers of an opponent.

We can incorporate testing into our decision-making processes by keeping track of outcomes in decision journals. Boyd's notes indicate that he may have done just that during his time as a fighter pilot, building up the knowledge that went on to form *Aerial Attack Study*. Rather than guessing how our decisions lead to certain outcomes, we can get a clear picture to aid us in future orientation stages. Over time, our decision journals will reveal what works and what doesn't.

Applying the OODA Loop

In sports, there is an adage that carries over to business quite well: "Speed kills." If you are able to be nimble, able to assess the ever-changing environment and adapt quickly, you'll always carry the advantage over your opponent.

Start applying the OODA loop to your day-to-day decisions and watch what happens. You'll start to notice things that you would have been oblivious to before. Before jumping to your first conclusion, you'll pause to consider your biases, take in additional information, and be more thoughtful of consequences.

As with anything you practice, if you do it right, the more you do it, the better you'll get. You'll start making better decisions more quickly. You'll see more rapid progress. And as John Boyd would prescribe, you'll start to DO something in your life, and not just BE somebody.

101. Break the Chain: Stop Being a Slave

A vendor once tried to buy me a laptop. Not just any laptop but a very expensive laptop. The vendor claimed that there were no strings attached. And, as they pointed out, I was the only person in the meeting with them, so “no one would know” they had given it to me. It wasn’t a hard decision. I said no. It wasn’t because I didn’t need a laptop. In fact, I did need one. The laptop I was using was old and out of date. I had purchased it myself years ago in a fit of frustration at the ridiculous process the government wanted me to follow to obtain one from them. *“No price is too high to pay for the privilege of owning yourself.”*

— Nietzsche

Governments have clear conflict-of-interest rules for people in situations like this one. The rules, however, are impractical. They’re also expensive. I remember one dinner with a vendor that ended up costing *me* hundreds of dollars personally. I made a mistake: I went to wash my hands around the time the vendor picked out some wine. I came back to see a glass of wine poured for me. When the bill came, the vendor insisted on paying it. Damaging our relationship and embarrassing him, I refused and said, “That’s very generous of you, but the government is clear; I’ve got to pay my share.”

My share? Over \$200. I hadn’t picked the restaurant or the wine. When I returned to work a few days later and submitted a claim for the difference between my per diem and the meal, I was literally laughed at.

But the real reason I said no to the laptop was that I don’t want to be owned by other people. Even if my freedom personally costs me money. However well-meaning the laptop offer might have been, I would have felt a debt to the vendor who’d given it to me. A debt that would need to be paid at some point. That debt would have created a bond between us that I didn’t want.

We need to make our own way, and there is a slippery slope between accepting the generosity of people who help you along and getting dependent on them. The entitlement born from expecting others to help you is a recipe for misery. So is excessive dependence on others.

The lesson is never to anticipate or rely on the kindness of strangers. This dependence means they own you. If you have a mortgage, you don’t own your house; the bank does. Working for the government taught me a lot about ownership — specifically, about dependence on other people. People refused to say what they really thought, subconsciously abiding by the maxim “whose bread I eat, his song I sing.”

When people would approach me and tell me how miserable they were and how they hated their jobs, I would ask them why they didn’t leave. The answer was almost always the same: “I can’t.”

Once we’re bought, it’s hard to get out. While we all start out wanting more independence, we increasingly live lifestyles that make us dependent.

When I first started working in the government, I made just under \$40k a year in salary. For me, just out of university, that was a killing. I felt like I could do whatever I wanted. After a while, I was making more money but still living off the same starting salary. The additional money went to savings and debt repayment. I said no to living above my means and watched as most of my friends couldn’t say no.

A lot of them spent more than they made no matter how many promotions they received. Appetites for desires are rarely quenched. As people spent more, they got more into debt. As they got more into debt, they wanted more and more. As their wants exceeded even the debt-funded shopping sprees (cars, trucks, houses, swimming pools, campers, play structures for the kids, etc.), they got unhappier. They saw other people with things they

wanted. Things they felt like they deserved. Their relationships suffered. They became miserable. They hated their jobs but they were stuck. The bank owned them. Work owned them.

And they realized it too late.

Part of the reason for the laptop offer was likely that vendor expected to have preferred access to me and to the government. Preferred access to information that could potentially benefit his company, to the tune of millions or tens of millions of dollars. Had I accepted the offer, it would have been hard to deny him. I saw the strings and didn't want any part of them.

Amelia Boone, the Michael Jordan of adventure racing, said, "I believe the key to self-sufficiency is breaking free of the mindset that someone, somewhere, owes you something and will come to your rescue."

The bank doesn't owe you a mortgage, just as work doesn't owe you a job.

"Self-sufficiency," wrote Epicurus, "is the greatest of all wealth." Epictetus added that "wealth consists not in having great possessions, but in having few wants."

It can be hard to say no. It means refusing someone, and often it means denying yourself instant gratification. The rewards of doing this are uncertain and less tangible. I call decisions like this "first-order negative, second-order positive." Most people don't take the time to think through the second-order effects of their choices. If they did, they'd realize that freedom comes from the ability to say no.

102. Strategy vs. Tactics: Why the Difference Matters

In order to do anything meaningful, you have to know where you are going.

Strategy and tactics are two terms that get thrown around a lot, and are often used interchangeably in numerous contexts. But what exactly do they mean, what is the difference, and why is it important? In this article, we will look at the contrast between strategy and tactics, and the most effective ways to use each.

While strategy and tactics originated as military terminology, their use has spread to planning in many areas of life. Strategy is overarching plan or set of goals. Changing strategies is like trying to turn around an aircraft carrier—it can be done but not quickly. Tactics are the specific actions or steps you undertake to accomplish your strategy. For example, in a war, a nation's strategy might be to win the hearts and minds of the opponent's civilian population. To achieve this they could use tactics such as radio broadcasts or building hospitals. A personal strategy might be to get into a particular career, whereas your tactics might include choosing your educational path, seeking out a helpful mentor, or distinguishing yourself from the competition.

We might have strategies for anything from gaining political power or getting promoted, to building relationships and growing the audience of a blog. Whatever we are trying to do, we would do well to understand how strategy and tactics work, the distinction, and how we can fit the two together. Without a strategy we run the risk of ambling through life, uncertain and confused about if we are making progress towards what we want. Without tactics, we are destined for a lifetime of wishful thinking or chronic dissatisfaction. As Lawrence Freedman writes in *Strategy: A History*, "Without a strategy, facing up to any problem or striving for any objective would be considered negligent. Certainly, no military campaign, company investment, or government initiative is likely to receive backing unless there is a strategy to evaluate.... There is a call for strategy every time the path to a given destination is not straightforward." And without tactics you become dependent on pure luck to implement your strategy.

To achieve anything we need a view of both the micro and the macro, the forest and the trees—and how both perspectives slot together. Strategy and tactics are complementary. Neither works well without the other. Sun Tzu recognized this two and a half millennia ago when he stated, "Strategy without tactics is the slowest route to victory. Tactics without strategy are the noise before defeat." We need to take a long-term view and think ahead, while choosing short-term steps to take now for the sake of what we want later.

The Relationship Between Strategy and Tactics

Any time we decide on a goal and invest resources in achieving it, we are strategizing. Freedman writes:

One common contemporary definition describes it as being about maintaining a balance between ends, ways, and means; about identifying objectives; and about the resources and methods available for meeting such objectives. This balance requires not only finding out how to achieve desired ends but also adjusting ends so that realistic ways can be found to meet them by available means.

In *The Grand Strategy of the Roman Empire*, Edward N. Luttwak writes that strategy "is not about moving armies over geography, as in board games. It encompasses the entire struggle of adversarial forces, which need not have a spatial dimension at all...." When you think about winning a war, what does it mean to actually win? History is full of examples of wars that were "won" on paper, only to be restarted as soon as the adversary had time to regroup. So being precise in your goal, to encompass the entirety of what you want to achieve, is necessary to articulate a good strategy. It's not about success in the moment, but success in the long term. It's the difference between the end of WWI and WWII. World War I was about winning that war. World War II was about never fighting a

war like that again. The strategies articulated and pursued by the Treaty of Versailles and the Marshall Plan were full of markedly different tactics.

In *Good Strategy, Bad Strategy*, Richard Rumelt writes: “The most basic idea of strategy is the application of strength against weakness. Or if you prefer, strength applied to the most promising opportunity...A good strategy doesn’t just draw on existing strength; it creates strength.” Rumelt’s definition of strategy as creating strength is particularly important. You don’t deplete yourself as you execute your strategy. You choose tactics that reinforce and build strength as they are deployed. Back to winning hearts and minds – the tactics require up-front costs. But as they proceed, and as the strategy unfolds, strength and further support are gained by having the support of the local population. A good strategy makes you stronger.

“Grand strategy is the art of looking beyond the present battle and calculating ahead. Focus on your ultimate goal and plot to reach it.”

— Robert Greene, *The 33 Strategies of War*

The Components of Strategy

The strategic theorist Henry Mintzberg provides a useful approach to thinking about strategy in adversarial situations. According to Mintzberg, there are five key components or types:

1. Plan: A consciously chosen series of actions to achieve a goal, made in advance.
2. Ploy: A deliberate attempt to confuse, mislead or distract an opponent.
3. Pattern: A consistent, repeated series of actions that achieve the desired result.
4. Position: A considered relationship between an entity (organization, army, individual etc) and its context.
5. Perspective: A particular way of viewing the world, a mindset regarding actions that lead to a distinct way of behaving.

Geoffrey P. Chamberlain offers a slightly different perspective on the components of strategy, useful when the strategy is more about a personal goal. He identifies seven parts:

1. A strategy is used within a particular domain.
2. A strategy has a single, well defined focus.
3. A strategy lays out a path to be followed.
4. A strategy is made up of parts (tactics).
5. Each of a strategy’s parts pushes towards the defined focus.
6. A strategy recognises its sphere of influence.
7. A strategy is either intentionally formed or emerges naturally.

According to Rumelt, a strategy must include “premeditation, the anticipation of others’ behavior, and the purposeful design of coordinated actions. As a general rule, strategy is more important in situations where other parties have the potential to thwart or disrupt actions, or where our plans are at risk if we don’t take meaningful steps to achieve them. Good strategy requires us to both focus on a goal, and anticipate obstacles to reaching that goal. When we encounter obstacles, we may need to employ what Freedman calls “deceits, ruses, feints, manoeuvres and a quicker wit”—our tactics.

“The skillful tactician may be likened to the Shuai-Jan. Now the Shuai-Jan is a snake that is found in the Ch’ang mountains. Strike at its head, and you will be attacked by its tail; strike at its tail, and you will be attacked by its head; strike at its middle, and you will be attacked by head and tail both.”

— Sun Tzu, The Art of War

A Few Words on Tactics

Even the most elegant, well-planned strategy is useless if we do not take thoughtful steps to achieve it. While the overall goal remains stable, the steps we take to achieve it must be flexible enough to adjust to the short-term realities of our situation.

The word “tactic” comes from the Ancient Greek “taktikos,” which loosely translates to “the art of ordering or arranging.” We now use the term to denote actions toward a goal. Tactics often center around the efficient use of available resources, whether money, people, time, ammunition, or materials. Tactics also tend to be shorter-term and more specific than strategies.

Many tactics are timeless and have been used for centuries or even millennia. Military tactics such as ambushes, using prevailing weather, and divide-and-conquer have been around as long as people have fought each other. The same applies to tactics used by politicians and protesters. Successful tactics often include an ‘implementation intention’—a specific trigger that signals when they should be used. Simply deciding what to do is rarely enough. We need an “if this, then that” plan for where, when and why. The short-term nature and flexibility of tactics allow us to pivot as needed, choosing the right ones for the situation, to achieve our larger, strategic goals.

If you don’t have a strategy, you are part of someone else’s strategy.”

— Alvin Toffler

Conclusion

Although often regarded as interchangeable, strategy and tactics are somewhat different, though complementary concepts. According to the skilled strategist Sun Tzu, strategy is about winning before the battle begins, while tactics are about striking at weakness. Both are ancient concepts that have come to be an essential part of numerous disciplines and offer endless new ways of thinking.

103. The Decision Matrix: How to Prioritize What Matters

The decisions we spend the most time on are rarely the most important ones. Not all decisions need the same process. Sometimes, trying to impose the same process on all decisions leads to difficulty identifying which ones are most important, bogging us down and stressing us out.

I remember once struggling at the intelligence agency shortly after I received a promotion. I was being asked to make too many decisions. I had no way to sort through them to figure out which ones mattered, and which ones were inconsequential.

The situation built slowly over a period of weeks. My employees were scared to make decisions because their previous boss had hung them out to dry when things went wrong. My boss, a political high flyer, also liked to delegate down the riskiest decisions. As a result, I had more decisions to make than capacity to make them. I was working longer and longer to keep up with the volume of decisions. Worse, I followed the same process for all of them. I was focusing on the most urgent decisions as the cost of the most important decisions.

It was clear to me that I wasn't the right person to make all of the decisions. I needed a quick and flexible framework to categorize decisions into the ones I should be making and the ones I should be delegating. I figured most of the urgent decisions could be made by the team because they were easily reversible and not very consequential. In fact, they were only becoming urgent because the team wasn't making the decisions in the first place. And because I was rushing through these decisions in an effort to put more time into the important decisions, I was making worse choices than the team would have.

As I was walking home one night, I came up with an idea that I used from the next day on, with pretty good success. I call it the Decision Matrix. It's a decision making version of the Eisenhower Matrix, which helps you distinguish between what's important and what's urgent. It's so simple you can draw it on a napkin, and once you get it, you get it.

While it won't make the decisions for you, it will help you quickly identify which decisions you should focus on.

The Decision Matrix

My strategy for triaging was simple. I separated decisions into four possibilities based on the type of decision I was making.

1. Irreversible and inconsequential
2. Irreversible and consequential
3. Reversible and inconsequential
4. Reversible and consequential

The great thing about the matrix is that it can help you quickly delegate decisions. You do have to do a bit of mental work before you start, such as defining and communicating consequentiality and reversibility, as well as where the blurring lines are.

The Decision Matrix in Practice

This matrix became a powerful ally to help me manage time and make sure I wasn't bogged down in decisions where I wasn't the best person to decide.

I delegated both types of inconsequential decisions. Inconsequential decisions are the perfect training ground to develop judgment. This saved me a ton of time. Before this people would come to me with decisions that were relatively easy to make, with fairly predictable results. The problem wasn't making the decision—that took seconds in most cases. The problem was the 30 minutes the person spent presenting the decision to me. I saved at least 5–7 hours a week by implementing this one change.

I invested some of that time meeting with the people making these decisions once a week. I wanted to know what types of decisions they made, how they thought about them, and how the results were going. We tracked old decisions as well, so they could see their judgment improving (or not).

Consequential decisions are a different beast. Reversible and consequential decisions are my favorite. These decisions trick you into thinking they are one big important decision. In reality, reversible and consequential decisions are the perfect decisions to run experiments and gather information. The team or individual would decide experiments we were going to run, the results that would indicate we were on the right path, and who would be responsible for execution. They'd present these findings.

Consequential and irreversible decisions are the ones that you really need to focus on. All of the time I saved from using this matrix didn't allow me to sip drinks on the beach.

Rather, I invested it in the most important decisions, the ones I couldn't justify delegating. I also had another rule that proved helpful: unless the decision needed to be made on the spot, as some operational decisions do, I would take a 30-minute walk first.

The key to successfully employing this in practice was to make sure everyone was on same page with the terms of consequential and reversible. At first, people checked with me but later, as the terms became clear, they just started deciding.

While the total volume of decisions we made as a team didn't change, how they were allocated within the team changed. I estimate that I was personally making 75% fewer decisions. But the real kicker was that the quality of all the decisions we made improved dramatically. People started feeling connected to their work again, productivity improved, and sick days (a proxy for how engaged people were) dropped.

Give the Decision Matrix a try—especially if you're bogged down and fighting to manage your time, it may change your working life.

104. Hemingway, a Lost Suitcase, and the Recipe for Stupidity

The best intentions are no match for the havoc caused by stress, tiredness, and unusual circumstances. Even though we know these things can negatively impact our decision-making abilities, we override the caution needed to combat them with faith in our rationality. This failure to recognize our natural vulnerabilities affects everyone. In December 1922, it resulted in a lost suitcase that changed Ernest Hemingway's life. Hemingway, then 23, wrote fiction at night while covering the Lausanne peace conference on assignment for the Toronto Daily Star. Married the year before, Hemingway missed his wife, Elizabeth Hadley Richardson, back in Paris. He asked her to join him in Lausanne. This invite resulted in all of Hemingway's work ending up in a suitcase.

"I have long held that stupidity is very largely the result of fear leading to mental inhibitions."

— Bertie Russell

It's unclear whether Hemingway asked Hadley to bring his work so he could show it to an editor who had taken an interest in him, or she brought it for another reason. Perhaps she thought he'd want to work on something over the Christmas break and wanted to give him all the options. Whatever the reason, the intentions were good. Hadley believed in Hemingway's talent as a writer, and she was financially supporting them so he could pursue his artistic goals.

Sick at the time, Hadley managed to pack everything she could find, including the originals, the carbon copies, and all handwritten notes for a novel in progress, into a single suitcase. When she arrived at Paris's Gare de Lyon, a porter offered to take her bags to her compartment. Right before the train was to depart, Hadley realized the journey would be long and rushed off the train to purchase a bottle of Evian, leaving the bags momentarily unattended. The suitcase was gone when she came back. Devastated, she cried for the entire eight-hour train ride.

Unaware of the loss, Hemingway waited for his wife at Lausanne station. When she arrived in tears, he said nothing warranted such sadness. Whatever was bothering her could be worked out together, he assured her. Hadley finally told him what had happened. Laughing, Hemingway told her not to worry because he had carbon copies of all of his writings. Hadley could barely bring herself to tell him that those too were lost. In disbelief, he rushed back to Paris. In his memoir of those years, *A Moveable Feast*, he recounted: "It was true alright and I remember what I did in the night after I let myself into the flat and found it was true." All his work was lost.

At this point, Hemingway wasn't the Hemingway we know today. None of his fiction had been published. Only two very short stories remained in Paris, "Up in Michigan"—which Gertrude Stein had called unpublishable—and "My Old Man," which was out with an editor at the time.

In a way that would make Marcus Aurelius proud, rather than give up, Hemingway found an interesting way to adapt to the reality of the situation. With the pressure of time, Hemingway shifted his writing style to shorter sentences, cleaner paragraphs and more readable prose. He could write faster this way. Four years later, *The Sun Also Rises* would be published and become a bestseller.

The lessons we can draw from Hemingway are obvious. It's a classic story of a struggling artist who has a setback but overcomes it to achieve huge success. Disney created a multibillion-dollar company on the back of stories like this one. But almost everyone misses the lessons—hiding in plain sight—offered by Hadley. And when it comes to avoiding catastrophic errors, we should pay close attention.

Most of us are not chronically stupid. We make many good decisions and accomplish some amazing things. But we commit acts of stupidity once in a while, usually when we fail to recognize how certain variables are making us vulnerable.

Stupidity is not the opposite of intelligence. My friend Adam Robinson has perhaps the best definition of stupidity I've come across, defining it as the overlooking or dismissing of conspicuously crucial information.

[quote]Stupidity is overlooking or dismissing crucial information.[/quote]

There are some things you should know about stupidity. Stupidity is easier to see in others than ourselves. Stupidity is easier to recognize the farther we are from the act. And stupidity is stubbornly difficult to see in the moment, often only becoming apparent when the outcome is known. This is why it is so important to recognize what the variables are that increase the chances of us doing something stupid. Stress, being tired, being in an unusual situation, these are all things that make us vulnerable to stupidity.

Back to our story: Hemingway shares some blame here, for not separating his originals and carbons. But more interesting are the details that affected Hadley's decisionmaking at the train station. She was outside of her normal environment. She was rushing. She was ill. Each of these things on their own can increase the odds of committing an act of stupidity. Combined, they meant she was significantly vulnerable to errors in judgment. Although Hemingway recovered, and arguably became a better writer because of it, the loss of his work was devastating to both him and his wife at the time. Only the benefit of hindsight gives this episode a decent ending, something that is no guarantee for most stupid decisions.

105. Defensive Decision Making: What IS Best vs. What LOOKS Best

“It wasn’t the best decision we could make,” said one of my old bosses, “but it was the most defensible.”

What she meant was that she wanted to choose option A but ended up choosing option B because it was the defensible default. She realized that if she chose option A and something went wrong, it would be hard to explain because it was outside of normal. On the other hand, if she chose option A and everything went right, she’d get virtually no upside. A good outcome was merely expected, but a bad outcome would have significant consequences for her. The decision she landed on wasn’t the one she would have made if she owned the entire company. Since she didn’t, she wanted to protect her downside. In asymmetrical organizations, defensive decisions like this one protect the person making the decision.

My friend and advertising legend Rory Sutherland calls defensive decisions the Heathrow Option. Americans might think of it as the IBM Option. There’s a story behind this:

A while ago, British Airways noticed a reluctance for personal assistants to book their bosses on flights from London City Airport to JFK. They almost always picked Heathrow, which was further away, and harder to get to. Rory believed this was because “flying from London City might be better on average,” but “because it was a non-standard option, if anything were to go wrong, you were much more likely to get it in the neck.”

Of course, if you book your boss to fly out of Heathrow—the default—and the flight is delayed, they’ll blame the airline and not you. But if you opted for the London City airport, they’d blame you.

At first glance, it might seem like defensive decision making is irrational. It’s actually perfectly rational when you consider the asymmetry involved. This asymmetry also offers insight into why cultures rarely change.

Some decisions place the decisionmakers in situations where outcomes offer little upside and massive downside. In these cases, it can seem like great outcomes carry a 1% upside, good outcomes are neutral, and poor outcomes carry at least 20% downside—if they don’t get you fired.

It’s easy to see why people opt for the default choice in these cases. If you do something that’s different—and thus hard to defend—and it works out, you’ve risked a lot for very little gain. If you do something that’s different and it doesn’t work out, and you might find yourself unemployed.

This asymmetry explains why your boss, who has nice rhetoric about challenging norms and thinking outside the box, is likely to continue with the status quo rather than change things. After all, why would they risk looking like a fool by doing something different? It’s much easier to protect themselves. Defaults give people a possible out, a way to avoid being held accountable for their decisions if things go wrong. You can distance yourself from your decision and perhaps be safe from the consequences of a poor outcome.

Doing the safe thing is not the same as doing the right thing. Often, the problem with the safe thing is that there is no growth, no innovation. It’s churning out more of the same. So in the short term, while you may think that the default is a better choice for your job security, in the long game there’s a negative. When you are unwilling to take risks, you stop recognizing opportunities. If you aren’t willing to put yourself out there for 1% gain, how do you grow? After all, the 1% upsides are more common than the 50% upsides. But in either case, if you become afraid of downside, then what level of risk would be acceptable? It’s not that choosing the default makes you a bad person. But a lifetime of opting for the default limits your opportunities and your potential.

And for anyone who owns a company, a staff full of default decision makers is a death knell. You get amazing results when people have the space to take risks and not be penalized for every downside.

106. How Not to Be Stupid

After a four-hour conversation on The Knowledge Project (Part 1, Part 2), Adam Robinson (@IAmAdamRobinson) and I shared another 10-minutes that shouldn't be missed on how not to be stupid.

Shane Parrish: Adam, you did a presentation once on how not to be stupid. Can you tell me about that? What is stupidity?

Adam Robinson: Right. It's so funny you should ask that, because people think stupidity is the opposite of intelligence. In fact, stupidity is the cost of intelligence operating in a complex environment. It's almost inevitable. And so I was asked by an organizer of an investment conference in the Bahamas of some elite global investors to do a talk on anything I wanted to do, except not about investing. It's just, pick an interesting topic. So I thought for a second and I blurt out, "Okay. How about how not to be stupid?" He laughed and he said, "Okay. Great." It took me a month of hard thinking, mind you, just to define stupidity. By the way, if you're in any field and you want to find ways to innovate, focus on words that are commonly used and try to define them simply.

It took me about a month, and I defined stupidity as overlooking or dismissing conspicuously crucial information. Right? It's crucial information, like you better pay attention to it. It's conspicuous, like it's right in front of your nose and yet you either overlook it or you dismiss it. How not to be stupid, what are the causes of human error—and it took me a couple of months of research just to come up with data points, because most stupidity is ignored or swept under the rug. I studied instances of scientific stupidity and literary stupidity and military stupidity and every other kind of stupidity, as well as two domains that engineer stupidity.

One is benign: magic. The magician misdirects your attention. The whole goal of the magician is to make you stupid, to not notice something you should have. The other is frauds and cons and hoaxes. That's also—but that's a malicious, malevolent kind of engineering of stupidity. The magician does so with our full consent, for entertainment purposes. The conman engineers stupidity for their own gain. I do historical research, everything, and I identify seven factors that lead to stupidity.

These seven factors are fascinating. In no particular order: one, being outside your normal environment or changing your routines. Two, being in the presence of a group. Three, being in the presence of an expert or if you, yourself, are an expert. Four, doing any task that requires intense focus. Five, information overload. Six, physical or emotional stress, fatigue. Seven—I'll come back to seven. I forget it right now. It's a few years. It'll come back to me in a second.

All seven factors are present in U.S. hospitals. All seven factors. This will astonish you. This was recently written about, but I don't think it's really dawned on people. In the United States every year, there are roughly 30,000 fatalities from automobile accidents. That is a benchmark. How many deaths accidentally occur, accidentally, in hospitals every year? In other words, you go in with a broken arm and you don't come out. Not, you died as a result of what you went in for. You died because of error, human error. I would tell you the current best estimate—this is deaths, mind you, not injuries—is 210 to 440 thousand people die every year in the United States from hospital error.

[quote]Stupidity is overlooking or dismissing conspicuously crucial information[/quote] (Editors note, that was not part of the conversation but will add context: When it comes to overloading our cognitive brains, the seven factors are: being outside of your circle of competence, stress, rushing or urgency, fixation on an outcome, information overload, being in a group where social cohesion comes into play, and being in the presence of an "authority." Acting alone any of these are powerful enough, but together they dramatically increase the odds you are unaware that you've been cognitively compromised.)

We know what to do, we just don't do it correctly. (Atul Gawande and I talk about this in [our interview](#)).

It's the third leading cause of death in the United States, right behind cancer and heart disease. If those seven factors—by the way, you don't need all seven factors to be present. They're additive. Oh, I remember what the final one was, and it's so funny I should forget it because it's the one that usually triggers stupidity. Rushing or a sense of urgency. So funny I would forget that one. It's usually the first one I say. By the way, if you're outside your normal environment and you are rushing, you are in big trouble, which is why often people are rushing on the way to the airport and they forget their passport or they do something. It has to do with information overload. All seven factors were present at the U.S. Challenger disaster. Remember back in 1986?

Didn't have to happen. All seven factors were present. There was the musician Yo-Yo Ma, in 1998 I believe, was rushing to an appointment in New York City. He lives in Boston. He was outside his normal environment, rushing, and he was preoccupied because he was late for an appointment. Three of the seven factors. You don't need all seven to create stupidity. In the back of the cab in which he's being driven is his million-dollar cello in a big blue Plexiglas thing. It's in the trunk. He gets out of the cab, he leaves it in the back of the trunk. All of a sudden, because Yo-Yo Ma is such a celebrity, the mayor is called, the police chief and all cars bulletin goes out, find this cello.

Cello?

They do. In the press conference, get this, he says, "I just did something stupid." I'm using air quotes. That's an exact phrase. "I just did something stupid. I was in a rush." Sure enough, in my research, I found three other situations where world class musicians were in a different city, rushing, and they left their instruments. Each one of them. One a \$3 million violin. He was on a national tour, left a \$3 million violin in an Amtrak train. Imagine \$3 million violin in the luggage compartment of an Amtrak train. Fortunately, they called ahead and they found it at the next station. He was lucky. Each of the musicians, in exactly the same—

Circumstance.

*—circumstances led to stupidity. Now, Atul Gawande wrote a book called [The Checklist Manifesto](#). Atul Gawande is brilliant. Brilliant, brilliant, brilliant. However, the problem with checklists is that the stupidity factors override them. The worst aviation disaster in history, *Shane*, occurred in 1977. Nearly 600 lives were lost when two planes collided during the day on the ground. Imagine, two planes collided in an airport on the ground. Six hundred lives were lost. You might say, how does that even happen? All seven factors were present. Something else. Do you know what the pilot that caused the crash was doing right before he took off and slammed into the plane? He was racing through a checklist.*

Checklists don't help you if you're stupid about the checklist. You're just not going to use it. A really important takeaway from that, and I'm so glad we got that final question in, is beware of rushing—and if these factors are present, don't make any important decisions. It doesn't take much. By the way, I mentioned fatigue and illness. If you're tired or emotionally overwrought, if you have pulled an all-nighter, you have the motor control and the reflex speed of someone who is legally drunk. An all-nighter you think, I mean we've all pulled all-nighters, right? We all sometimes pull multiple all-nighters.

You gotta be aware. You may think that cognitively you're okay, but your motor control skills and your reflexes are those of someone who's legally drunk. You've really got to be careful. By the way, multitasking is information overload. That comes under the information overload thing, and if you're talking on Bluetooth while you're driving a car, you have exponentially increased the odds that you're going to get into an accident.

This is why when you're lost, the first thing you do is turn down the radio.

Oh, fascinating. You're right.

When you're in a car, when you get lost, you always...one of the first things you do is eliminate an input, which is the radio.

That's so funny. You're right.

Or if you're talking with somebody you say, "Hold on a second," because you intuitively know that that's just—subconsciously, you know that's distracting you.

By the way, that's so funny you should mention that, because that's why when I tell people that statistic about...talking on Bluetooth on the phone when you're driving is incredibly dangerous. People say, "Yeah, but what about if someone's in the front of the seat talking to you?" That in fact doubles your odds. If someone's in the front seat with you, talking while you're driving, you've doubled the chances of your getting into an accident. Just doubled. Just that, but the difference is that that person, when you are dealing with unusual traffic conditions, he or she will shut up.

Right, they can see it.

They can see it. The person on the phone who's talking on Bluetooth doesn't shut up.

You're still getting the input. That's why it's so dangerous.

That's really interesting. I never thought of that.

Yeah. Well, I didn't think about it until I researched it.

107. The Anatomy of a Great Decision

Making better decisions is one of the best skills we can develop. Good decisions save time, money, and stress. Here, we break down what makes a good decision and what we can do to improve our decision-making processes.

Improving our decision-making abilities is a central goal at Farnam Street. Better decisions save time, money, and stress. While it's an investment now, in the long run, learning principles and developing a multidisciplinary lens that we can apply throughout life is a worthy investment.

As we have said before, a decision should not be judged solely on its outcome.

Sometimes good decisions produce bad results. A recruiting process that has resulted in mostly excellent candidates will still occasionally fail to weed out a bad fit. It is impossible to have perfect and complete information for all the variables involved. So we do the best with what we have.

Using a decision journal can move us to that place where we are consistently making better decisions. At its core, the technique of identifying and reflecting on process from beginning to end helps us achieve the two main qualities in better decisions:

1. Using principles, not tactics
2. Looking at a situation through a multidisciplinary lens

These qualities are what we need to improve over time. And in the same way compounding interest increases our bank balance, better decisions produce exponentially better results the more of them we make. Hard decisions today, made well, prepare us to make decisions more easily in the future.

When we look around, however, to see what we can learn from others who made great decisions, we often judge based solely on the outcomes. Whether a decision by a family member to buy Coca-Cola stock in the '80s, or Caesar to cross the Rubicon, we evaluate a decision as good based on how things turned out.

Evaluating decisions on outcomes prevents us from learning. We need to dive into a decision, cut it open and examine its parts. Regardless of what happened, learning how a decision was made is the place to find knowledge. So what does the anatomy of a great decision look like?

// Evaluating
decisions on
outcomes
prevents us from
learning. //

fs

The Marshall Plan

After WWII, Europe was in ruins. Much of the infrastructure had been destroyed. Many people were starving, and had lost everything they possessed. Those systems we take for granted, but on which we rely daily—transportation, manufacturing, agriculture—had been devastated. The economies were essentially broken, and the countries that saw a lot of fighting had much to rebuild. But with what money? Many countries were in serious debt. Continued, widespread economic hardships were on the horizon.

In 1947, Secretary of State General George Marshall put forward a plan that has since carried his name, a plan to give a massive amount of money to several European nations. Those countries accepted, the continent was rebuilt, and Marshall is credited with one of the most positive defining acts of economics, politics, and ethics in the last century. But when you look at the thinking that went into the Marshall Plan, the reasoning behind the details, you see that it would have been a great decision regardless of the outcome.

Asking the Right Questions

At the beginning, participants asked questions. What do we want to achieve? What problems are we addressing? What does a successful outcome look like?

From there came the principles, things like: strong economies minimize social unrest; countries that work toward mutual goals are less likely to fight each other; let's not have another war in Europe anytime soon.

Starting from these principles, decision makers evaluated the situation through a multidisciplinary lens. Economics, politics, humanitarian responsibilities, historical and psychological factors—the plan sought to address issues on many fronts and took a wide perspective into account.

The plan was developed in the State Department of the United States. It was not the work of a single individual, and contributions from many people made it into the final version that Marshall fought for in Congress.

In the end, there were three key decisions made in terms of the structure of the plan:

1. To give, versus lend, the majority of the aid
2. To require the nations receiving the aid to work out how to allocate it
3. To invite Russia to partake

Using Multiple Lenses

The decision to give rather than lend the majority of the aid was the result of looking at the situation through economic, political, and humanitarian lenses. It was also a win-win.

Immediately following the war, the European nations had put significant effort into restarting their economies. But they were doing it with borrowed dollars, needing to import far more than they were capable of exporting. Many economies needed modernization, which was impossible to fund while paying for imports at the same time. Without full economic recovery in Europe, there was great danger of a recession, or even a second depression. Basically, Europe needed money.

But economies are also about people. It is people who produce and consume and develop the economy. So it wasn't just the countries that needed financial assistance, but the people in them. The designers of the plan knew that hungry, desperate people would only create more social unrest. They saw that if they didn't give the money to Europe they might very well have to spend it on national security as Europe fell apart.

And we can't discount the impact of the physical reality of the aftermath of the war that the liberating forces confronted—starving people, towns reduced to rubble. The case for humanitarian assistance was strong.

Letting the World Do the Work For You

The decision to have the participating nations allocate the aid among themselves was the answer to what the historical, political and psychological lenses revealed.

Many people felt that the approach to reparations after WWI was a significant impetus for WWII. The First World War had a similar effect on the economies and infrastructures of the nations involved. In 1918, angry at Germany, France and Britain had demanded huge sums of money. The problem was, it essentially crippled Germany economically, and caused a social and political situation that created enmity among the European nations. Many argue that it was this series of events that produced a situation in which Hitler could come to power.

The creators of the Marshall Plan were aware of this, and it was one of the elements that influenced the design of the terms. If Germany collapsed again, they might be fighting World War III in twenty years.

By asking enemies to work together and approve each other's share, the plan created a buy-in that defused much of the anger and animosity between the nations. Just a couple of years earlier they had been at war with each other. After sacrificing so much in both lives and money, it was natural that the various peoples were angry over both who started the war, and the many violent and destructive events that were enacted over those six years.

But the US decided to not take sides and extend the alliances of the war. The plan creators realized this wouldn't help fulfill the principles they had chosen to abide by. Europe working meant Europe working together.

Outcomes Over Optics

Inviting Russia to share in the aid was another important result of applying those political, historical, psychological, and humanitarian lenses.

The end of WWII marked the beginning of the Cold War. More nebulous by nature, starting a couple of years after the liberation of Europe and the dropping of the atomic bomb, this political climate would shape international relations for the next 40 years. The Marshall Plan took into account how best to navigate this complicated territory. Russia had been a valuable ally during the war, holding the eastern front and inflicting considerable damage on Hitler's efforts. But immediately post-war their actions demonstrated a desire to at least influence, if not control, the political structure of the world. Their version of communism was at direct odds with US democracy, and was thus considered a legitimate threat. Even though there was very little expectation that Russia would participate, and possibly even less desire to give them money, Russia and its allied countries were invited by both the US and the European nations to participate in the talks involving the implementation of the plan. They chose not to, and followed up with accusing the plan of being a front to American imperialist goals. This was important because it forced Russia's hand. They could not later claim that the Iron Curtain was something that was thrust on them. It was, instead, something they deliberately chose to build.

The Marshall Plan is remembered as a great decision, not strictly because of its outcomes—though it did contribute to the debatably successful reconstruction of Europe, it did not succeed in preventing the deterioration of relations with Russia—but because it was firmly grounded in principles that were identified and executed through a multidisciplinary lens.

108. Externalities: Why We Can Never Do “One Thing”

No action exists in a vacuum. There are ripples that have consequences that we can and can't see. Here are the three types of externalities that can help us guide our actions so they don't come back to bite us.

An externality affects someone without them agreeing to it. As with unintended consequences, externalities can be positive or negative. Understanding the types of externalities and the impact they have in our lives can help us improve our decision making, and how we interact with the world.

Externalities provide useful mental models for understanding complex systems. They show us that systems don't exist in isolation from other systems. Externalities may affect uninvolved third parties which make them a form of market failure—an inefficient allocation of resources.

We both create and are subject to externalities. Most are very minor but compound over time. They can inflict numerous second-order effects. Someone reclines their seat on an airplane. They get the benefit of comfort. The person behind bears the cost of discomfort by having less space. One family member leaves their dirty dishes in the sink. They get the benefit of using the plate. Someone else bears the cost of washing it later. We can't expect to interact with any system without repercussions. Over time, even minor externalities can cause significant strain in our lives and relationships.

The First Law of Ecology

To understand externalities it is first useful to consider second-order consequences.

In *Filters Against Folly*, Garrett Hardin describes what he considers to be the First Law of Ecology: We can never do one thing. Whenever we interact with a system, we need to ask, “And then what? What will the wider repercussions of our actions be?” There is bound to be at least one externality.

Hardin gives the example of the Prohibition Amendment in the U.S. In 1920, lawmakers banned the production and sale of alcoholic beverages throughout the entire country. This was in response to an extended campaign by those who believed alcohol was evil. It wasn't enough to restrict its consumption—it needed to go.

The addition of 61 words to the American Constitution changed the social and legal landscape for over a decade. Policymakers presumably thought they could make the change and people would stop drinking. But Prohibition led to numerous externalities. Alcohol is an important part of many people's lives. Few were willing to suddenly give it up without a fight. The demand was more than strong enough to ensure a black-market supply re-emerged.

Wealthy people stockpiled alcohol in their homes before the ban went into effect.

Thousands of speakeasies and gin joints flourished. Walgreens grew from 20 stores to 500, in large part due to its sales of ‘medicinal’ whiskey. Former alcohol producers simply sold the ingredients for people to make their own. Gangsters like Al Capone made their fortune smuggling, and murdered his rivals in the process. Crime gangs undermined official institutions. Tax revenues plummeted. People lost their jobs. Prisons became overcrowded and bribery commonplace. Thousands died from crime and drinking unsafe homemade alcohol.

Policymakers did not fully ask, “And then what?” before legislating. Drinking did decrease during this time, on average by about half. But this was far from the hope of a total ban. The second-order consequences outweighed any benefits.

As economist Gregory Mankiw explains in *Principles of Microeconomics*,

In the presence of externalities, society's interest in a market outcome extends beyond the well-being of buyers and sellers who participate in the market; it also includes the well-being of bystanders who are affected indirectly.... The market equilibrium is not efficient

when there are externalities. That is, the equilibrium fails to maximize the total benefit to society as a whole.

Negative Externalities

Negative externalities can occur during the production or consumption of a service or good. Pollution is a useful example. If a factory pollutes nearby water supplies, it causes harm without incurring costs. The costs to society are high and are not reflected in the price of whatever the factory makes. Economists often view environmental damage as another factor in a production process. But even if pollution is taxed, the harmful effects don't go away.

Transport and manufacturing release toxins into the environment, harming our health and altering our climate. The reality though, is these externalities are hard to see, and it is often difficult to trace them back to their root causes. There's also the question of whether we are responsible for externalities or not.

Imagine you're driving down the road. As you go by an apartment, the noise disturbs someone who didn't agree to it. Your car emits air pollution, which affects everyone living nearby. Each of these small externalities will affect people you don't see and who didn't choose them. They won't receive any compensation from you. Are you really responsible for the externalities you cause? If you're not being outright careless or malicious, isn't it just part of life? How much responsibility do we have as individuals, anyway?

Calling something a negative externality can be a convenient way of abdicating responsibility.

Positive Externalities

A positive externality imposes an unexpected benefit on a third party. The producer doesn't agree to this, nor do they receive compensation for it.

Scientific research often leads to positive externalities. Research findings can have applications beyond their initial scope. The resulting information becomes part of our collective knowledge base. However, the researcher who makes a discovery cannot receive the full benefits. Nor do they necessarily feel entitled to them.

Blaise Pascal and Pierre de Fermat developed probability theory to solve a gambling dispute. Their work went on to inform numerous disciplines (like the field of calculus) and transform our understanding of the world. Probabilities are now a core part of how we think. Pascal and Fermat created a positive externality.

Someone who comes up with an equation cannot expect compensation each time it gets used. As a result, the incentives to invest the time and effort to discover new equations are reduced. Algorithms, patents, and copyright laws change this by allowing creators to protect and profit from their ideas for years before other people can freely use them. We all benefit, and researchers have an incentive to continue their work.

Network effects are an example of a positive externality. Silicon Valley understands this well. Each person who joins a network, like a marketplace app, increases the value to all other users. Those who own the network have an incentive improve it to encourage new users. Everyone benefits from being able to communicate with more people. While we might not join a new network intending to improve it for other people, that is what normally happens. (On the flipside, network effects can also produce negative externalities, as too many members can decrease the value of a network.)

Positive externalities often lead to the "free rider" problem. When we enjoy something that we aren't paying for, we tend not to value it. Not paying can remove the incentive to look after a resource and leads to a Tragedy of the Commons situation. As Aristotle put it, "For that which is common to the greatest number has the least care bestowed upon it." A good portion of online content succumbs to the free rider problem. We enjoy it and yet we don't pay for it. We expect it to be free and yet, if users weren't willing to support sites like Farnam Street, they would likely fold, start publishing lower quality articles, or sell readers to advertisers who collect their data. The end result, as we see too frequently, is low-

quality content funded by page-view advertising. (This is why we have a membership program. Members create a positive externality for non-members by helping support the free content.)

Positional Externalities

Positional externalities are a form of second-order effects. They occur when our decisions alter the context of future perception or value.

For example, consider what happens when a person decides to start staying at the office an hour late. Perhaps they want a promotion and think it will endear them to managers. Parkinson's Law states that tasks expand to fit the time allocated to them. What this person would otherwise get done by 5pm, now takes until 6pm. Staying late becomes their norm. Their co-workers notice and start to also stay late. Before long, staying at the office until 6pm becomes the standard for everyone. Anyone who leaves at 5pm is perceived as lazy. Now that 6pm is the norm, everyone suffers. They are forced to work more without deriving any real benefits. It's a lose-lose situation for everyone.

Someone we know once made an investment with a nearly unlimited return by gaming the system. He worked for an investment firm that valued employees according to a perception of how hard they worked and not necessarily by their results. Each Monday he brought in a series of sport coats and left them in the office. He paid the cleaning staff \$20 a week to change the coat hanging on his chair and to turn on his computer. No matter what happened, it appeared he was always the first one into the office even though he often didn't show up from a "client meeting" until 10. When it came to bonus time, he'd get an enormous return on that \$20 investment.

Purchasing luxury goods can create positional externalities. Veblen goods are items we value because of their scarcity and high cost. Diamonds, Lamborghinis, tailor-made suits — owning them is a status symbol, and they lose their value if they become cheaper or if too many people have them. As Luca Lambertini puts it in *The Economics of Vertically Differentiated Markets*,

The utility derived from consumption is a function of the quantity purchased relative to the average of the society or the reference group to whom the consumer compares." In other words, a shiny new car seems more valuable if all your friends are driving battered old wrecks. If they have equally (or more) fancy cars, the value of yours drops. At some point, it seems worthless and it's time to find a new one. In this way, the purchase of a Veblen good confers a positional externality on other people who own it too.

That utility can also be a matter of comparison. A person earning \$40,000 a year while their friends earn \$30,000 will be happier than one earning \$60,000 when their friends earn \$70,000. When someone's salary increases, it raises the bar, giving others a new point of reference.

We can confer positional externalities on ourselves by changing our attitudes. Let's say someone enjoys wine but is not a connoisseur. A \$10 bottle and a \$100 bottle make them equally happy. When they decide to go on a course and learn the subtleties and technicalities of fine wines, they develop an appreciation for the \$100 wine and a distaste for the \$10. They may no longer be able to enjoy a cheap drink because they raised their standards.

Conclusion

Externalities are everywhere. It's easy to ignore the impact of our decisions—to recline an airplane seat, to stay late at the office, or drop litter. Eventually though, someone always ends up paying. Like the villagers in Hardin's *Tragedy of the Commons*, who end up with no grass for their animals, we run the risk of ruining a good thing if we don't take care of it. Keeping the three types of externalities in mind is a useful way to make decisions that won't come back to bite you. Whenever we interact with a system, we should remember to ask Hardin's question: and then what?

109. Preserving Optionality: Preparing for the Unknown

We're often advised to excel at one thing. But as the future gets harder to predict, preserving optionality allows us to pivot when the road ahead crumbles.

How do we prepare for a world that often changes drastically and rapidly? We can preserve our optionality.

We don't often get the advice to keep our options open. Instead, we're told to specialize by investing huge hours in our passion so we can be successful in a niche.

The problem is, it's bad advice. We live in a world that's constantly changing, and if we can't respond effectively to those changes, we become redundant, frustrated, and useless. Instead of focusing on becoming great at one thing, there is another, counterintuitive strategy that will get us further: preserving optionality. The more options we have, the better suited we are to deal with unpredictability and uncertainty. We can stay calm when others panic because we have choices.

Optionality refers to the act of keeping as many options open as possible. Preserving optionality means avoiding limiting choices or dependencies. It means staying open to opportunities and always having a backup plan.

An option is usually defined as something we have the freedom to choose. That's a fairly broad definition. In the context of a strategy, it must also have a limited downside and an open-ended upside. Betting in a casino is not an option, for example—the upside is known. Losses and gains are both constrained. What about betting on a new tech startup? That's an option—the upside is theoretically unlimited; the losses are limited to the amount you invest.

Options present themselves all the time, but life-altering ones often come up during times of great change. These options are the ones we have the hardest time capitalizing on. If we've specialized too much, change is a threat, not an opportunity. Thus, if we aren't certain where the opportunities are going to be (and we never are), then we need to make choices to keep our options open.

Baron Rothschild is often quoted as having said that "the time to buy is when there's blood in the streets." That's a misquote, however. What he actually said was "buy when there's blood in the streets, even if the blood is your own." Rothschild recognized that those are the times when new options emerge. That's when many investors make their fortunes and when entrepreneurs innovate. Rothschild saw opportunity in chaos. He made a fortune buying during the panic after the Battle of Waterloo.

When we occupy a small niche, we sacrifice optionality. That means less freedom and greater dependency. No one can predict the future—not even experts—so isn't it a good idea to have as many avenues open as possible?

The coach's dilemma: strength vs. optionality

In Simple Rules: How to Thrive in a Complex World, Kathleen Eisenhardt and Donald Sull describe the experience of strength coach Shannon Turley. For the uninitiated, the role of a strength coach is to help athletes stay healthy and perform better, rather than teach specific skills.

Turley began his career working at Virginia Polytechnic Institute and State University.

When he started, the football players there followed a strength program based on weightlifting alone. Athletes wore t-shirts listing their personal records and competed to outdo each other. The mantra was: get stronger by lifting more weight.

But Turley soon realized that this program was not effective because it left the athletes with limited optionality. Turley found no correlation between weightlifting prowess and competitive performance. Being able to bench press a lot of weight didn't serve them well on the football field. As he put it, "In football if you're on your back, you've already lost."

Keeping a record of what he saw, he began looking for different options for the athletes.

After gaining experience coaching in several sports, Turley realized that strength was not the most important factor for athletic success. What mattered for any type of athlete was staying free of injuries and good nutrition. Why? Because that gave athletes greater optionality.

An uninjured, healthy player could stay in each game for longer and miss fewer training sessions. It also meant less chance of requiring surgery, which many of his students faced, or of being forced to retire from competitive sports at a young age.

Turley began coaching football players at Stanford University. He implemented a program focusing on proper nutrition and flexibility exercises such as yoga—not weightlifting. He also focused on healing existing injuries that restricted athletes' performance. One football player he worked with had ongoing back problems, so Turley designed a regime to improve that issue. It worked: the athlete never missed a game and went on to play in the NFL. Turley's approach served to preserve optionality for his players. Even the best athlete will lose many competitions. So the more an athlete is healthy enough to participate in games, the greater the chances of those crucial successes. Turley's experience illustrates the trade-offs between particular physical abilities and optionality.

Over-specializing in one area is highly limiting, especially if it requires extensive upkeep.

Like a football player, we can retain optionality by avoiding overtly damaging risks and ensuring we stay in the game for as long as possible—whatever that game is. That might mean lifting less metaphorical weight at any one time, while also working to keep ourselves flexible.

The tyranny of small decisions

Few people would deliberately lock themselves into an undesirable situation. Yet we often make small, rational decisions that end up removing options over time. This is the tyranny of small decisions. Economist Alfred Kahn identified the concept in 1966. Kahn begins the article with a provocative thought experiment:

Suppose, 75 years ago, some being from outer space had made us this proposition: "I know how to make a vehicle that could in effect put 200 horses at the disposal of each of you. It would permit you to travel about, alone or in small groups, at 60 to 80 miles an hour. But the costs of this gadget are 40,000 lives per year, global warming, the decay of the inner city, endless commuting, and suburban sprawl." What would we have chosen collectively?

Put that way, the answer, of course, is no—we wouldn't choose the advancement of transportation technology if we could immediately see the grievous cost. But we have said yes to that exact offer over time through a million small decisions, and now it is difficult to back out. Most of the modern world is built to accommodate cars. Driving is now the "rational" choice, no matter the destructive effect. Sometimes it feels as though we have no other option.

Kahn's point is that small decisions can lead to bad outcomes. At some point, alternatives disappear. We lose our optionality. It is easy to see the downsides of big decisions. The costs of smaller ones can be more elusive. In a market economy, Kahn explains, change is the result of tiny steps. Combined, they have a tremendous cumulative effect on our collective freedom. Day to day, it is hard to see the path that is forming. At some point, we may look up and not like where we are going. By then it is too late. Kahn writes:

Only if consumers are given the full range of economically feasible and socially desirable alternatives in a big discrete bundle will misallocation of resources due to the tyranny of small market-determined decisions be broken.

The tragedy of the commons is another such instance of the power of small decisions.

Garett Hardin's parable illustrates why common resources are used more than is desirable from the standpoint of society as a whole. No one person makes a single decision to deplete the resources. Instead, each person makes a series of small choices that ultimately cause environmental ruin. In the original example where villagers are freely able

to graze their animals on common land, having access to it gives everyone a lot of options for raising animals or farming. Once the pasture is exhausted from everyone putting too many animals out to graze, however, everyone loses their optionality.

Optionality can be a matter of perspective

As Seneca put it, “In one and the same meadow, the cow looks for grass, the dog for a hare, and the stork for a lizard.” Where some people only see blood in the streets, other people see a chance to succeed.

Preserving optionality can be as much about changing our attitudes as our circumstances. It can be about learning to spot opportunities—and to make them. Optionality is not a new concept. A portion of the Old Testament dating back to between 450 and 180 BCE declares:

Invest in seven ventures, yes, in eight; you do not know what disaster may come upon the land. If clouds are full of water, they pour rain on the earth. Whether a tree falls to the south or to the north, in the place where it falls, there it will lie. Whoever watches the wind will not plant; whoever looks at the clouds will not reap . . . Sow your seed in the morning, and at evening let your hands not be idle, for you do not know which will succeed, whether this or that, or whether both will do equally well.

In today’s world, optionality can be integrated into a number of different areas of our lives by looking for ways to prepare for a variety of possible events, instead of optimizing for the recent past.

Keeping our options open means developing generalist skills like creativity, rather than specializing in one area, like a particular technology. The more diverse the knowledge and skills you can draw on, the better positioned you are to take advantage of new opportunities.

It means not relying on a single distributor for your company’s product or having the supply chain for an entire industry dependent on one country. You can’t make your decisions solely on how the world was yesterday. Preserving optionality means you may take a short-term hit in sales by funding diversity, but the result is you will be much better positioned in the future to keep your business going when circumstances change.

It means not relying on a single energy source to power the vehicles that move us and the goods we need around. Building our society around oil—a finite resource—is limiting. Developing multiple forms of sustainable energy creates new options for when that finite resource is depleted.

Or consider the lean startup methodology. Building a minimum viable product means having the flexibility to pivot or change plans. No demand? No problem! Just try something else. Lean startups iterate until they find product/market fit. Many founders keep their teams as small as possible. They avoid fixed costs and commitments. They keep their options open.

The lean startup methodology recognizes that a new company cannot make a grand plan; it needs to adapt and evolve. As Steve Jobs understood, most customers don’t know they will want something until they have tried it. It’s hard to prepare for changing customer desires without optionality. If a company is flexible, they can adapt to the information they receive once a product hits the market.

“Wealth is not about having a lot of money; it’s about having a lot of options.”

— Chris Rock

Ultimately, preserving optionality means paying attention and looking at life from multiple perspectives. It means building a versatile base of foundational knowledge and allowing for serendipity and unexpected connections. We must seek to expand our comfort zone and circle of competence, and we should take minor risks that have potentially large upsides and limited downsides.

Paradoxically, preserving optionality can mean saying no to a lot of opportunities and avoiding anything that will prove to be restrictive. We need to look at choices through the lens of the optionality they will give us in the future and only say yes to those that create more options.

Preserving your optionality is important because it gives you the flexibility to capitalize on inevitable change. In order to keep your options open, you need diversity. Diversity of perspective, thought, knowledge, and skills. You don't want to find yourself in a position of only being able to sell something that no one wants. Rapid, extraordinary change is the norm. In order to adapt in a way that is useful, keep your options open.

Making decisions and applying mental models in the real world involves a systematic approach that combines critical thinking, analysis, and creativity. Here's a step-by-step guide to help you make decisions and apply mental models effectively:

Steps for Making Decisions and Applying Mental Models:

1. Define the Decision to Be Made:

- Clearly define the decision you need to make, including the problem or question you're trying to address and the desired outcome.

2. Identify Relevant Mental Models:

- Consider which mental models might be applicable to the decision-making process based on the nature of the problem or question.
- Choose mental models that offer insights or frameworks that align with the decision you're facing.

3. Gather Information and Data:

- Collect relevant information and data related to the decision from reliable sources.
- Use research, analysis, and observation to gather insights that will inform your decision-making process.

4. Analyze the Decision Using Mental Models:

- Apply the relevant mental models to analyze the decision from different perspectives.
- Use the frameworks provided by the mental models to organize your thoughts, identify patterns, and evaluate potential outcomes.

5. Consider Alternative Perspectives:

- Explore alternative viewpoints and consider how different mental models might lead to different conclusions or approaches.
- Use critical thinking to weigh the pros and cons of each perspective and consider their implications for the decision.

6. Evaluate Potential Solutions or Courses of Action:

- Generate potential solutions or courses of action based on the insights gained from applying mental models.
- Use logical reasoning and analysis to evaluate the feasibility, effectiveness, and potential risks of each option.

7. Make a Decision:

- Based on your analysis and evaluation, make a decision that aligns with your goals, values, and priorities.
- Choose the option that offers the best balance of benefits, risks, and alignment with the mental models applied.

8. Implement the Decision:

- Develop a plan for implementing the decision, including specific actions, timelines, and responsibilities.
- Use project management tools and techniques to track progress and ensure accountability.

9. Monitor and Evaluate:

- Monitor the implementation of the decision closely and evaluate its effectiveness over time.
- Use feedback, data analysis, and reflection to assess whether the decision is achieving the desired outcomes and adjust course as needed.

10. Reflect and Learn:

- Reflect on the decision-making process and outcomes, considering what worked well and what could be improved.
- Learn from your experiences and apply lessons learned to future decision-making efforts.

11. Iterate and Improve:

- Continuously refine your decision-making skills and apply new mental models as you encounter different challenges and opportunities.
- Seek out feedback, training, and resources to enhance your ability to make informed and effective decisions.

By following these steps, you can systematically approach decision-making and apply mental models to gain deeper insights, make more informed choices, and achieve better outcomes in the real world.

Making decisions in a complex world and within complex systems requires a nuanced approach that acknowledges uncertainty, interdependencies, and dynamic interactions. Here are steps to guide you through the process:

Steps for Making Decisions in a Complex World and Complex Systems:

1. Acknowledge Complexity:

- Recognize the complexity of the world and the systems within it. Understand that factors influencing decisions are often interconnected and dynamic.

2. Define the Decision Context:

- Clearly define the decision you need to make and understand the broader context in which it exists.

- Consider the various stakeholders, objectives, constraints, and uncertainties involved.

3. **Gather Diverse Perspectives:**

- Seek input from a diverse range of stakeholders, experts, and perspectives to gain a comprehensive understanding of the decision context.
- Encourage open dialogue and collaboration to uncover different viewpoints and insights.

4. **Map the System:**

- Map out the complex system relevant to the decision, identifying key components, relationships, and feedback loops.
- Use tools such as systems diagrams, causal loop diagrams, or network analysis to visualize the system's structure and dynamics.

5. **Identify Leverage Points:**

- Identify potential leverage points within the system where interventions or changes could have significant impact.
- Consider both high-leverage interventions that target key systemic drivers and low-leverage interventions that address specific symptoms or outcomes.

6. **Apply Systems Thinking:**

- Use systems thinking principles to understand how actions and decisions may affect the broader system over time.
- Consider the potential unintended consequences and feedback loops that could arise from different courses of action.

7. **Anticipate Uncertainty:**

- Acknowledge and embrace uncertainty, recognizing that outcomes may be unpredictable due to the complexity of the system.
- Use scenario planning, sensitivity analysis, or simulation modeling to explore different possible futures and their implications.

8. **Evaluate Trade-offs:**

- Recognize that decisions in complex systems often involve trade-offs between competing objectives, interests, and values.
- Evaluate these trade-offs transparently and ethically, considering both short-term and long-term implications.

9. **Embrace Iterative Learning:**

- Approach decision-making as an iterative process of learning and adaptation.
- Be willing to experiment, monitor outcomes, and adjust course based on feedback and new information.

10. **Engage in Adaptive Governance:**

- Implement adaptive governance structures and processes that allow for flexibility, responsiveness, and learning.
- Foster collaboration, transparency, and accountability in decision-making processes.

11. **Communicate Effectively:**

- Communicate the rationale behind your decisions clearly and transparently to stakeholders.
- Use storytelling, visualization, and other techniques to convey complex concepts and trade-offs in a way that is understandable and compelling.

12. **Reflect and Learn Continuously:**

- Reflect on the outcomes of your decisions and the effectiveness of your decision-making processes.
- Encourage a culture of continuous learning and improvement, where lessons from past decisions inform future actions.

By following these steps, you can navigate the complexities of the world and make decisions that are informed, adaptive, and effective within complex systems.

Step 84- Thinking, Logic and Mental Model

1. Listen, Follow and Apply Thinking, Logic and Mental Model PART 7

Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- 12. Step 68-Journaling. Pages 1306.**
- 13. Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

Step 85- Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works.
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman.**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.
- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding

how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding

Step 86-Journaling

1. **Step 1-So keep a journal. Write your experiences down. When you identify a model at work in the world, write that down too. Then you can explore the applications you've observed, and start being more in control of the models you use every day. For instance, instead of falling victim to confirmation bias, you will be able to step back and see it at work in yourself and others. Once you get practice, you will start to naturally apply models as you go through your life, from reading the news to contemplating a career move. As we have seen, we can run into problems when we apply models to situations in which they don't fit. If a model works, we must invest the time and energy into understanding why it worked so we know when to use**
2. **Visualization- Remember, visualization will never compensate for the work undone. You cannot visualize lies. All the strategies I employ to answer the simple questions and win the mind game are effective because I put in work. It's a lot more than mind over matter. It takes relentless self-discipline to schedule suffering into your day, every day, but if you do, you'll find that at the other end of that suffering is a whole other life just waiting for you.**
 - **First, he would learn everything he could about it and prepare physically as best as possible.**
 - **Once the physical prep was done, he'd take care of the mental prep with visualization.**
 - **Since he knew almost everything about his challenge, he visualized what awaited him. He would imagine himself struggling, suffering, and eventually succeeding.**
 - **Preparing himself this way helped him pace his future, and improve the odds of avoiding quitting.**
 - **Side note: visualization is great, but it's no substitute for preparation.**

Step 87-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. **The world never tells you that you're wrong; it only gives you outcomes.**
3. **Don't force. Don't resist. Have a beginner's mind. Let the world teach you.**
4. **Reality will do a lot of the work for us if we simply align with it. Most of the time we're simply adding friction because we want the world to work in the way we think it should.**
5. **If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman.**
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or

circumstances. If you want to align yourself with reality, you have to work at it and care about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.

- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated,

example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so

afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

PART 13: Deep Work and Communication

Step 88-Slow Down

- 1. Do Not Rush Any Tasks I will do At Any Time.**
- 2. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”**
- 3. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.**

- I. We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- II. The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- III. But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- IV. Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- V. We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- VI. As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always seems that the time-train is

pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

VII. Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.

VIII. When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.

IX. The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom — the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one

French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- X. Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don't go away never to be seen again. It's not like we make a bad decision and we're done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we're doing more.

4. Do The Tasks Slowly, and Step By Step.

5. The Art of Slowing down and Do Not Rush Anything.

- I. The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we're going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- II. Too many of us see going nowhere as turning away from something rather than turning towards something.
- III. Going nowhere isn't about turning your back on the world; it's about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- IV. The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it's how we respond to our experiences, not the experiences themselves, which shape us.
- V. The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- VI. “Our creations come not when we're out in the world, gathering impressions, but when we're sitting still, turning those impressions into sentences.

Step 89-NOT MULTITASK.

1. Of course you can do more than one thing at once. The catch is you can't do more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time. When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.
2. There is a mental cost—called a switching cost—to all of this multitasking. But that's not all it makes deep thinking impossible.
3. I think people that multitask pay a huge price. They think they're being extra productive, and I think they're (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don't have time to think about anything deeply. You're giving the world an advantage you shouldn't do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can't succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
4. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: "You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube."
5. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don't do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.
6. Listen and Apply The Following Books:

A. The Multitasking Mind By Dario Saliveci

Step 90-You Have Required To Do The Work For Communication.

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very very hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

- I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.
- II. First Left Hand Column Are My Arguments.
- III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.
- IV. Third Left Column are My Responses to the Opponent responses.
- V. Fourth Left Hand Column are My Rebuttal.
- VI. Fifth Left Hand Column are Opponent Rebuttal.
- VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.
- VIII. Seventh Left Hand Column is the Final My Rebuttal.
- IX. Eight Left Hand Column is The opponent Rebuttal.
- X. Ninth Left Hand Column is my closing statements.
- XI. Tenth Left Hand Column is the opponent closing statements.
- XII. Eleventh Left Hand Column is the Cross Examination.
 - My Answer.
 - Opponent Answer.
 - My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 91-Use Rules of Reading for Communication

1. Listen, Follow and Apply Rules of Reading of Bible Study, Deep Work, Deep Study, Analysis, Syntopicon and Research For Decision Making.
 - A. **VERY VERY FAST Reading- Skimming. Pages 47-51.**
 - B. **VERY FAST READING- Entertainment.**
 - I. **Method 1-Speed Reading. FAST Reading. Pages 59-64.**
 - C. **FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.**
 - I. **Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**
 - II. **Method 2-Use 80/20 Principle For Reading. Pages 68.**
 - III. **Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.**
 - IV. **Method 4-Flip Through Pages and Analyse. Page 70.**
 - V. **Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.**
 - VI. **Method 6-Devotional Bible Read. Pages 73-74.**

D. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**
- VIII. Method 8-Book Survey Method. Pages 195-205.**
- IX. Method 9-Chapter Analysis Method. Pages 206-215.**
- X. Method 10-Paragraph Study. Pages 216-229.**
- XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- XII. Method 12-Book Synthesis Method. Pages 235-238.**
- XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- XIV. Method 14-Studying Bible Prophecy. Pages 246-259.**
- XV. Method 15-Typological Study Method. Pages 260-262.**
- XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- XVII. Method 17-Inductive Bible Study Method. Pages 269-296.**
- XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

E. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

2. Apply The Books For Communication.

Step 92 - Communication Books

1. Person Has 2 Ears and 1 mouth. Therefore, The person needs to listen minimum twice more than speak. Ask Questions, Ask for clarification, Ask Myself If I understood his position in full. Try to understand the person position by restated in my own words, and Ask them to confirm or deny if I correctly stated the person position. Ask Myself, if this is logical, and the proposition leads to the conclusion. Ask Myself if I agree with the person position. Ask Myself What could be the weak point of this position.
2. One of The Most Important Traits and Features of Person are Being Critical Thinker and Think Before Speak in Any Situation in Life.
3. Better To Keep Silence and Be Thought A Fool than To Open Your Mouth and Remove all Doubt.
4. Take A moment to Think Before Speaking, to construct exactly what you wanted to tell without variously sentences. Do not be like most of the people feel the need to say the first thing that comes to mind rather taking a moment to break down the question and forming the best answer possible.
5. Never Rush yourself and anybody when communicating to answer the question, but let the person take a moment to break down the question and forming the best answer possible.
6. Absolutely do not believe anything you hear and only half of what you see.
7. What is the Key Of Story Teller: True answer that not that you do not have story. You have so many stories in your life. It is because you do not document them. To be great storyteller, you must first become, great collectors of stories. So You need to do, start new note on the paper story bank, and next time in your life something that emotionally moves you, capture it. Like interaction with colleague. Use 5w and 1h and dialogue
 - A. Who
 - B. What
 - C. Where
 - D. When
 - E. How
 - F. Dialogue
 - G. Capture the story, and before you know it, and before you know it a story a day.

8. **Listen, Follow And Apply Rules of Reading Part 1 to 11, before looking into Communication.**
9. **Listen, Follow and Apply the following Books.**
 - A. **How To Read A Book By Mortimer Adler Various Editions**
 - B. **Socratic Method**
 - C. **Preaching.**
 - I. **EXPOSITORY PREACHING.**
 - II. **Homiletic _ moves and structures.**
 - III. **Homiletics.**
 - IV. **Homiletics or the Theory of Preaching.**
 - V. **How to Speak How to Listen.**
 - VI. **Preaching _ the art of narrative exposition.**
 - VII. **The Art & Craft of Biblical Preaching_ A Comprehensive Resource for Today's Communicators.**
 - VIII. **Tactics and Socrates Method.**
 - D. **Public Speaking.**
 - I. **A Pocket Guide to Public Speaking.**
 - II. **Confessions of a Public Speaker.**
 - III. **Confident Public Speaking.**
 - IV. **How to Develop Self-Confidence And Influence People By Public Speaking.**
 - V. **How to Speak How to Listen.**
 - VI. **No Sweat Public Speaking!_ How to Develop, Practice, and Deliver a Knock Your Socks Off Presentaton! with No Sweat.**
 - VII. **Public Speaking Handbook.**
 - VIII. **Tactics_ A Game Plan for Discussing Your Christian Convictions.**
 - IX. **The Complete Guide to Public Speaking.**
 - X. **The Confident Speaker.**
 - XI. **The Everything Public Speaking Book. Deliver a Winning Presentation Every Time.**
 - XII. **The Official TED Guide to Public Speaking.**
 - XIII. **Voice and Speaking Skills For Dummies.**
 - XIV. **Tactics and Socrates Method.**
 - XV. **Media Argumentation_ Dialect, Persuasion and Rhetoric.**

- XVI. Power, Persuasion and Manipulation in Specialised Genres_ Providing Keys to the Rhetoric of Professional.**
- XVII. How to win every Argument: the art of Debating and Public Speaking**

Step 93- Thinking, Logic and Mental Model

1. Listen, Follow and Apply Thinking, Logic and Mental Model PART 7

Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- 1. Step 57- Slow Down. Pages 1061-1063.**
- 2. Step 58- NOT MULTITASK. Pages 1064.**
- 3. Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
- 4. Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
- 5. Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
- 6. Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
- 7. Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
- 8. Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
- 9. Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
- 10. Step 66-Journaling. Pages 1299.**
- 11. Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
- 12. Step 68-Journaling. Pages 1306.**
- 13. Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

Step 94-Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. The world never tells you that you're wrong; it only gives you outcomes.
3. Don't force. Don't resist. Have a beginner's mind. Let the world teach you.
4. **Reality will do a lot of the work for us if we simply align with it.** Most of the time we're simply adding friction because we want the world to work in the way we think it should.
5. If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care

about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.
- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything

outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models

allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself "If I do X, what will happen *after* that?". I sum this up using the ecologist Garrett Hardin's simple question: "And then what?" A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves "And then what?" We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they "reorganize their incentive programs," but practically, they've simply expended energy to stay in place. Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's

got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do

put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

PART 14: Deep Work and Teach

Step 95-Slow Down

- 1. Do Not Rush Any Tasks I will do At Any Time.**
- 2. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”**
- 3. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.**

- I. We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- II. The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- III. But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- IV. Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- V. We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- VI. As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always seems that the time-train is

pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

VII. Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.

VIII. When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.

IX. The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom — the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one

French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- X. Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don't go away never to be seen again. It's not like we make a bad decision and we're done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we're doing more.

4. Do The Tasks Slowly, and Step By Step.

5. The Art of Slowing down and Do Not Rush Anything.

- I. The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we're going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- II. Too many of us see going nowhere as turning away from something rather than turning towards something.
- III. Going nowhere isn't about turning your back on the world; it's about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- IV. The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it's how we respond to our experiences, not the experiences themselves, which shape us.
- V. The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- VI. “Our creations come not when we're out in the world, gathering impressions, but when we're sitting still, turning those impressions into sentences.

Step 96-NOT MULTITASK.

1. Of course you can do more than one thing at once. The catch is you can't do more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time. When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.
2. There is a mental cost—called a switching cost—to all of this multitasking. But that's not all it makes deep thinking impossible.
3. I think people that multitask pay a huge price. They think they're being extra productive, and I think they're (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don't have time to think about anything deeply. You're giving the world an advantage you shouldn't do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can't succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
4. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: "You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube."
5. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don't do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.
6. Listen and Apply The Following Books:

A. The Multitasking Mind By Dario Saliveci

Step 97-You Have Required To Do The Work For Teaching.

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very very hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. The Art of Anticipation of Objections.

- A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
- B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
- C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
- D. Use Think, Logic, Strategem, Thinking models.
- E. Write.
- F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
- G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
- I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts that ran contrary to his ideas, he endeavored not only to listen but also not to rest

until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

9. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.

II. First Left Hand Column Are My Arguments.

III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.

IV. Third Left Column are My Responses to the Opponent responses.

V. Fourth Left Hand Column are My Rebuttal.

VI. Fifth Left Hand Column are Opponent Rebuttal.

VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.

VIII. Seventh Left Hand Column is the Final My Rebuttal.

IX. Eight Left Hand Column is The opponent Rebuttal.

X. Ninth Left Hand Column is my closing statements.

XI. Tenth Left Hand Column is the opponent closing statements.

XII. Eleventh Left Hand Column is the Cross Examination.

- My Answer.

- Opponent Answer.

- My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Be Honest.

G. Be Open Minded.

H. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

I. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.

J. Never Take Cheap Shots at the Opponent.

- K. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- L. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 98-Use Rules of Reading for Teaching

1. Listen, Follow and Apply Rules of Reading of Bible Study, Deep Work, Deep Study, Analysis, Syntopicon and Research For Teaching.

A. VERY VERY FAST Reading- Skimming. Pages 47-51.

B. VERY FAST READING- Entertainment.

I. Method 1-Speed Reading. FAST Reading. Pages 59-64.

C. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.

I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.

II. Method 2-Use 80/20 Principle For Reading. Pages 68.

III. Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.

IV. Method 4-Flip Through Pages and Analyse. Page 70.

V. Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.

VI. Method 6-Devotional Bible Read. Pages 73-74.

D. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**
- VIII. Method 8-Book Survey Method. Pages 195-205.**

- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

E. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

2. Apply The Books For Teaching

Step 99-Teaching Books

1. **Listen, Follow And Apply Rules of Reading Part 1 to 12, before looking into Teaching.**
2. **Listen, Follow and Apply the following Books.**
 - A. **How to Read A Book bY Mortimer Adler Various Editions**
 - B. **Socratic Method and Logic**
 - C. Building a Better Teacher_ How Teaching Works.
 - D. Does Socrates Have a Method___ Rethinking the Elenchus in Plato's Dialogues and Beyond.
 - E. Socrates and the Socratic Dialogue.
 - F. Socrates_and_Philosophy_in_the_Dialogues_of_Plato.
 - G. Socratic Circles_ Fostering Critical And Creative Thinking In Middle And High School.
 - H. Socratic Ignorance and Platonic Knowledge in the Dialogues of Plato.
 - I. Socratic Teaching Method (A Textbook for_ Socratic Questions 101.
 - J. Tactics and Socrates Method.
 - K. Teaching Psychology and the Socratic Method_ Real Knowledge in a Virtual Age.
 - L. Teaching to Learn, Learning to Teach.
 - M. The art of teaching art _ a guide for teaching and learning the foundations of drawing-based art.
 - N. How Learning Works.
 - O. Learning to Read Critically in Teaching and Learning (Learning to Read Critically Series).
 - P. Teaching to Learn, Learning to Teach.
 - Q. The-role-of-socratic-questioning-in-thinking-teaching-and-learning.
 - R. THE_SOCRATIC_METHOD_AS_AN_APPROACH_IN_TEACHING_SOCIAL_STUDIES_A_LITERATURE_REVIEW.
 - S. Heather Coffey_Socratic method.
 - T. EXPERIENCE-EDUCATION-JOHN-DEWEY.

 - V. Platos Socrates as Educator
 - W. Redefining Scientific Thinking for Higher Education
 - X. Socratic Method In The Classroom.

Y. Teaches Like Socrates

Z. The Power of Socratic Classroom

AA. Thinker Guide of Socratic Questioning

BB.Socratic Logic__ A Logic Text using Socratic Method, Platonic Questions, and Aristotelian Principles.

CC.The Art of Asking Essential Questions_ Based on Critical Thinking Concepts and Socratic Principles.

DD.Socratic Method Today

Step 100- Thinking, Logic and Mental Model

1. Listen, Follow and Apply Thinking, Logic and Mental Model PART 7

Part 7: Thinking, Logic and Mental Model For Deep Work or Deep Study, Or Bible Study

- 1. Step 57- Slow Down. Pages 1061-1063.**
- 2. Step 58- NOT MULTITASK. Pages 1064.**
- 3. Step 59-You Have Required To Do The Work For Thinking and Applying Mental Tool Models. Pages 1065-1080.**
- 4. Step 60-Why Critical Thinking, Logic, Thinking and Mental Tools Are Important? Pages 1081-1083.**
- 5. Step 61-Intradisciplinary Thinking. Pages 1084-1125.**
- 6. Step 62-Multidisciplinary Thinking. Pages 1126-1168.**
- 7. Step 63-CrossDisciplinary Thinking. Pages 1169-1211.**
- 8. Step 64-Interdisciplinary Thinking. Pages 1212-1254.**
- 9. Step 65-Transdisciplinary Thinking. Pages 1255-1298.**
- 10. Step 66-Journaling. Pages 1299.**
- 11. Step 67-Letting The World Do The Work For You. Pages 1300-1305.**
- 12. Step 68-Journaling. Pages 1306.**
- 13. Step 69-Letting The World Do The Work For You. Pages 1307-1312.**

Step 101-Teach.

Teach

- A. Let The People Ask Questions and Use Socratic Method.**
- B. Additionally, Be Honest and Transparent at all time, if I do not know, then let the people know that I do not know.**
- C. Always be humble.**
- D. Lead the people to the truth, by asking them to never criticise the idea, without fully investigated. Ask Them to read, and use Rules of reading to find out the answers.**
- E. Never discourage the person, but encourage the person and lets investigate this question together to find the answer.**
- F. Primary Goal of this step is to take stock of all the knowledge we have acquired and teach it to someone else.**
- G. Pause and think carefully, before Talking, Speaking, Communicating For Following Reasons:**
 - **Use How to Read A Book Rules and Steps by Mortimer Addler for Various Editions**
 - **Socratic Logic, Method AND Questioning.**
 - **Think How Will I Say this.**
 - **Think What Words Will I Use Communicating.**
 - **Think The way I will Respond.**
 - **Think Why would I say and respond this way.**
 - **Think, If this is logical what will I say**
 - **Think, If this is reality what I am saying, Responding and Communicating.**
 - **Think, If there are Questions might arise?**
 - **Think of Questions, I might ask?**
- H. Teaching can be done through different means:**
 - **Videos, Audio Podcast, Writing, Conversation, Speeches**
- I. The crucial point is that you need to collect all the information you have gathered and attempted to articulate it in simple words that can be grasped by someone wholly unfamiliar with the topic.**

J. This step will force your mind to organise your knowledge in a way that can be utilised more practically. The importance of this step lies in the fact that when you try to reorganise and pass on all the information you have, you'll inevitably discover gaps in your understanding that will compel you to revise your resources to plug them. It will also ingrain your knowledge on a deeper level, due to the massive difference between simply regurgitating acquired knowledge and understanding it enough to be able to teach someone else.

K. Method of Teaching.

- Compile a Youtube video on the larger topic.
- Create presentation or blogpost.
- Write a book chapter or something else.
- Conversation with someone.

Step 102 - Letting The World Do The Work For You

1. Listen and Apply book
 - I. This Explains Everything_ Deep, Beautiful, and Elegant Theories of How the World Works
2. The world never tells you that you're wrong; it only gives you outcomes.
3. Don't force. Don't resist. Have a beginner's mind. Let the world teach you.
4. **Reality will do a lot of the work for us if we simply align with it.** Most of the time we're simply adding friction because we want the world to work in the way we think it should.
5. If you don't see the world the way it is, you'll think it works in a way that it doesn't and make terrible mistakes. The key to getting what you want out of life is to identify how the world works and align yourself accordingly. This is hard because we think the world should work the way we see it. The word "should" is important. Because we think the world should work in a way that it doesn't, our approach is suboptimal. What the pupil must learn, if he learns anything at all, is that the world will do most of the work for you, provided you cooperate with it by identifying how it really works and aligning with those realities. If we do not let the world teach us, it teaches us a lesson. Joseph Tussman
6. When an outcome is not what you want it to be, things get tough. You can ignore the result and continue to think that you're right. This protects your ego. It also carries the risk of your continuing to believe something that isn't true. Alternatively, you can calibrate your believability on the subject at hand by lowering the odds that you're right. For example, maybe you gave yourself an 85 out of 100 for the ability to hold a firm opinion on this subject, and now you lower your score to 75. If the world continues to provide undesirable outcomes, eventually you get the hint and change your beliefs. Finally, you can give up your opinions and just respond to the world as it is. This option is the hardest.
7. You do not create the way the world works, you can only align yourself with it. It takes a lot of work to align ourselves with reality. When we don't get the outcome we're seeking, the last place we look is inside ourselves. Instead, we blame others or circumstances. If you want to align yourself with reality, you have to work at it and care

about it. There are two keys to aligning yourself with how the world really works: accepting feedback and stopping bargaining.

- I. We let people, not results, guide our behavior. The world tries to tell us when we don't see it the way it is. The problem is we don't listen to the world. Instead, we let others tell us what's right and wrong, what works, and what doesn't. Common actions get common results. Most of our actions come from others. We want what they want. Even worse, we employ the same actions to get it. This isn't always wrong. If you're just starting, the quickest path to average is to copy. If you want better results than average, you're going to have to iterate. Doing something different means we might look like a fool, and we do not want to look like a fool. Iterating means trying something new, it means you might fail. Show me a person who's afraid to look bad, and I'll show you a person you can beat every time. If we do what everyone else is doing, we're going to get the same results that everyone else is getting. Different results demand different actions. If you can't really fail, you can't really succeed. Let results, not popularity, determine your actions. If you're doing something that doesn't get you the results you want, try something new. If you're doing something that seems to work, keep doing it. Consistently repeat successful actions.
- II. Bargaining with the world doesn't work. A lot of otherwise smart people know what they're doing isn't getting the results they want, but because they think the world *should* work in a way that it doesn't, they keep repeating them hoping for different results. If you are this person, see it for what it is, and change your actions. The feedback from the world is often painful. Often, it is this very pain that causes us to no longer delude ourselves with how the world should work and accept how it does work. If you can learn to accept the world for how it is, before suffering, you'll go faster and further. Outcome over ego. If you think you know how the world works but you're doing something that gets suboptimal results because it *should* work a different way, you don't really know how the world works. Rational people take feedback from the world. If you want to know how someone sees the world, look at their actions. In the end, it's all your fault. You are accountable for your outcomes. When you take responsibility for your outcomes, you naturally accept feedback from reality. When you get feedback from reality, you adjust your behavior.
- III. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything

outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of you, then the world becomes your library to help you to become better at the craft.

- IV. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position.
- V. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.
- VI. If you understand the world as it really is, not as you'd wish it to be, you will begin to make better decisions almost immediately. Once you start making better decisions the results compound. Better initial decisions free up your time, reduce your stress, allowing you to spend more time with your family and leave your competition in the dust.
- VII. How can we best understand the world as it is? Acquiring knowledge can be a very daunting task. If you think of the mind as a toolbox, we're only as good as the tools at our disposal. A carpenter doesn't show up to work with an empty toolbox. Not only do they want as many tools in their toolbox as possible, but they want to know how to use them. Having more tools and the knowledge of how to use them means they can tackle more problems. Try as we might, we cannot build a house with only a hammer. If you're a knowledge worker, you're a carpenter. But your tools aren't bought at a store and they don't come in a red box that you carry around. Mental tools are the big ideas from multiple disciplines, and we store them in our mind. And if we have a lot of tools and the knowledge required to wield them properly, we can start to synthesize how the world works and make better decisions when confronted with problems.
- VIII. This is how we understand and deal with reality. The tools you put into your toolbox are Mental Models. Mental models are a framework for understanding how the world really works. They help you grasp new ideas quickly, identify patterns before anyone else and shift your perspective with ease. Mental Models

allow us to make better decisions, scramble out of bad situations, and think critically. If you want to understand reality you must look at a problem in multiple dimensions — how could it be otherwise? Getting to this level of understanding requires having a lot of tools and knowing how to use them. You knew there was a hitch right? We need to change our fast-food diet of information consumption and adopt the healthier diet of knowledge that changes slowly over time. While changing diets isn't easy, it can be incredibly rewarding: more time, less stress, and being better at your job. The costs, however, are short term pain for long-term gain. You must change how you think.

- IX. 2nd Order Thinking. One example of a model we can immediately conceptualize and use to improve our ability to make better decisions is something we can borrow from ecology called second-order thinking. The simple way to conceptualize this is to ask yourself “If I do X, what will happen *after* that?”. I sum this up using the ecologist Garrett Hardin's simple question: “And then what?” A lot of people forget about higher order effects — second and third-order effects or higher. I've been in a lot of meetings where decisions are made and very few people think to the second level, let alone the third. Rather, what typically happens is called first conclusion bias. The brain shuts down and stops thinking at the first idea that comes to mind that seems to address the problem as you understand it. We don't often realize that our first thoughts are usually not even our own thoughts. They usually belong to someone else. We understand the sound-byte but we haven't done the hard work of real thinking. After we reach the first conclusion, our minds often shut down. We don't seek evidence that would contradict our conclusion. We don't ask ourselves what the likely result of this solution would be — we don't ask ourselves “And then what?” We don't ask what other solutions might be even *more* optimal. For example, consider a hypothetical organization that decides to change their incentive systems. They come up with a costly new system that requires substantial changes to the current system. Only they don't consider (or even understand) the problems that the *new* system is likely to create. It's possible they've created more problems than they've solved — only now there are *different* problems they must put their head down to solve. Optically, they “reorganize their incentive programs,” but practically, they've simply expended energy to stay in place. Another, perhaps more complicated, example is when a salesman comes into a company and offers you a software program he claims will lower your operating costs and increase your profits. He's

got all these beautiful charts on how much more competitive you'll be and how it will improve everything. This is exactly what you need because your compensation is based on increasing profits. You're sold. Then second-order thinking kicks in and you dare to ask how much of those cost savings are going to go to you and how much will eventually end up benefits enjoyed by customers? To a large extent, that depends on the business you're in. However, you can be damn sure the salesman is now knocking on your competitor's door and telling them you just bought their product and if they want to remain competitive they better purchase it too. Eventually, you all have the new software and no one is truly better off. Thus, in the manner of a crowd of people standing on their tip-toes at a parade, all competitors spend the money but none of them win: The salesman wins and the customer wins. We know, thanks to people like Garrett Hardin, Howard Marks, Charlie Munger, Peter Kaufman, and disciplines like ecology, that there are second and third-order effects. This is how the world really works. It just isn't always a comfortable reality. Understanding how the world works isn't easy and it shouldn't be. It's hard work. If it were easy, everyone would do it. And it's not for everyone. Sometimes, if your goal is to maximize utility, you should focus on getting very, very good in a narrow area and becoming an expert, accepting that you will make many mistakes outside of that domain. But for most, it's extremely helpful to understand the forces at play outside of their narrow area of expertise. Because when you think about it, how could reality be anything other than a synthesis of multiple factors? How could it possibly be otherwise?

- X. When our mental models line up with reality, they help us avoid problems. However, they also cause problems when they don't line up with reality as we think something that isn't true.
- XI. We must be open to other perspectives if we truly want to understand the results of our actions. Despite feeling that we've got all the information, if we're on the ship, the fish in the ocean has more he can share. The second flaw is ego. Many of us tend to have too much invested in our opinions of ourselves to see the world's feedback—the feedback we need to update our beliefs about reality. This creates a profound ignorance that keeps us banging our head against the wall over and over again. Our inability to learn from the world because of our ego happens for many reasons, but two are worth mentioning here. First, we're so afraid about what others will say about us that we fail to put our ideas out there and subject them to criticism. This way we can always be right. Second, if we do

put our ideas out there and they are criticized, our ego steps in to protect us. We become invested in defending instead of upgrading our ideas. The third flaw is distance. The further we are from the results of our decisions, the easier it is to keep our current views rather than update them. When you put your hand on a hot stove, you quickly learn the natural consequence. You pay the price for your mistakes. Since you are a pain avoiding creature, you update your view. Before you touch another stove, you check to see if it's hot. But you don't just learn a micro lesson that applies in one situation. Instead, you draw a general abstraction, one that tells you to check before touching anything that could potentially be hot. Organizations over a certain size often remove us from the direct consequences of our decisions. When we make decisions that other people carry out, we are one or more levels removed and may not immediately be able to update our understanding.

PART 15: Deep Work and Writing

Step 103-Slow Down

- 1. Do Not Rush Any Tasks I will do At Any Time.**
- 2. Listen and Apply Book “The Slow Fix Solve Problems, Work Smarter, and Live Better in a World Addicted to Speed”**
- 3. Listen and Apply Book *In Praise Of Slowness Challenging the Cult of Speed BY Carl Honore.**

- I. We live in a world scarce of understanding and abundant with information. We complain that we never have any free time yet we seek distraction. If work can't distract us, we distract ourselves. We crave perpetual stimulation and motion. We're so busy that our free time comes in 20 second bursts, just long enough for us to read the gist and assume we understand. If we are to synthesize learning and understanding we need time to think.
- II. The modern storm of bits and stimulation, relents only when we sleep. (And then only if we remember to turn off the phone.) Lost in all of this is the art of stillness. We live in a world with more information than ever and yet we understand less. We have come into the belief that the simple act of reading confers understanding. Worse, most of our reading is elementary reading, or skimming — a far cry from syntopical reading, which seems more fertile for the mind willing to do the work.
- III. But that's just it. We don't want, or can't find the time, to do the work that's required to hold an opinion. It's much easier to simply read the opinions of another and let them think for us.
- IV. Understanding comes from focusing, chewing, and relentlessly ragging on a problem. It comes with false starts, dead ends, and frustration. Thinking requires time and space. It's slow. It means saying I don't know. In short, thinking is everything the modern workplace is designed to eradicate.
- V. We're expected to have an opinion about everything and yet our time to think is near zero. We hold more opinions than ever but have less understanding. We don't even understand ourselves. How could it be otherwise?
- VI. As Milan Kundera wrote in his 1996 novella Slowness, “When things happen too fast, nobody can be certain about anything, about anything at all, not even about himself. “In our fast-moving modern world, it always seems that the time-train is

pulling out of the station just as we reach the platform. No matter how fast we go, no matter how cleverly we schedule, there are never enough hours in the day.”

VII. Carl Honore, wrote a book, In Praise of Slowness: Challenging the Cult of Speed, to explore why we’re always in such a rush, what if anything is the cure for time-sickness, and whether it’s desirable to slow down. The book is not an all-out declaration of war against speed. Speed has helped to remake our world in ways that are wonderful and liberating. Who wants to live without the Internet or jet travel? The problem is that our love of speed, our obsession with doing more and more in less and less time, has gone too far; it has turned into an addiction, a kind of idolatry. Even when speed starts to backfire, we invoke the go-faster gospel.

VIII. When we rush, we skim the surface, and fail to make real connections with the world or other people.” Moreover we don’t make connections with ideas. We don’t synthesize. We don’t test theories over time. We don’t play with ideas.

IX. The implications on thinking are fascinating. We are all fast-thinkers now. We have forgotten how to look forward to things, and how to enjoy the moment when they arrive. Restaurants report that hurried diners increasingly pay the bill and order a taxi while eating dessert. Many fans leave sporting events early, no matter how close the score is, simply to steal a march on the traffic. Then there is the curse of multi-tasking. Doing two things at once seems so clever, so efficient, so modern. And yet what it often means is doing two things not very well. Like many people, I read the paper while watching TV— and find that I get less out of both. In this media-drenched, data-rich, channel-surfing, computer-gaming age, we have lost the art of doing nothing, of shutting out the background noise and distractions, of slowing down and simply being alone with our thoughts. Boredom — the word itself hardly existed 150 years ago— is a modern invention. Remove all stimulation, and we fidget, panic and look for something, anything, to do to make use of the time. When did you last see someone just gazing out the window on a train? Everyone is too busy reading the paper, playing video games, listening to iPods, working on the laptop, yammering into mobile phones. Instead of thinking deeply, or letting an idea simmer in the back of the mind, our instinct now is to reach for the nearest sound bite. In modern warfare, correspondents in the field and pundits in the studio spew out instant analyses of events as they occur. Often their insights turn out to be wrong. But that hardly matters nowadays: in the land of speed, the man with the instant response is king. With satellite feeds and twenty-four-hour news channels, the electronic media is dominated by what one

French sociologist dubbed “le fast thinker”— a person who can, without skipping a beat, summon up a glib answer to any question.

- X. Fast eats time. One consequence of fast is that we make poor decision after poor decision. Those decisions don't go away never to be seen again. It's not like we make a bad decision and we're done with it. No, the consequences are much worse. Poor decisions eat time. They come back to haunt you. They create issue after issue. They feed into the perpetual motion machine of busyness. And in a culture where people wear busyness as a badge of honor bad decisions actually lead us to think that we're doing more.

4. Do The Tasks Slowly, and Step By Step.

5. The Art of Slowing down and Do Not Rush Anything.

- I. The Art of Stillness is a persuasively argued case for the pleasures of slowing down and being in one place. Today we're going faster and faster in search of contentment and meaning. This is largely a recipe for ensuring we will never be happy. We have the sense, too often, of running at top speed and never being able to catch up.
- II. Too many of us see going nowhere as turning away from something rather than turning towards something.
- III. Going nowhere isn't about turning your back on the world; it's about stepping away now and then so that you can see the world more clearly and love it more deeply. “There is nothing either good or bad, but thinking makes it so.”
- IV. The idea behind choosing to sit still long enough to learn about yourself is simple and has been around for ages. Marcus Aurelius and Epictetus reminded us many millennia ago that it's how we respond to our experiences, not the experiences themselves, which shape us.
- V. The greatest weapon against stress is our ability to choose one thought over another. Part of making better decisions is making time to think. Something that few of us are able to do.
- VI. “Our creations come not when we're out in the world, gathering impressions, but when we're sitting still, turning those impressions into sentences.

Step 104 - NOT MULTITASK.

1. Of course you can do more than one thing at once. The catch is you can't do more than one thing at once that requires concentration. You can walk and chew gum, but you can't write an email and a report at the same time. When you're doing two things at once that are cognitively demanding, what you're really doing is switching back and forth very quickly from one task to another.
2. There is a mental cost—called a switching cost—to all of this multitasking. But that's not all it makes deep thinking impossible.
3. I think people that multitask pay a huge price. They think they're being extra productive, and I think they're (out of their mind). I use the metaphor of the one-legged man in the ass-kicking contest. I think when you multi-task so much, you don't have time to think about anything deeply. You're giving the world an advantage you shouldn't do. Practically everybody is drifting into that mistake. Concentrating hard on something that is important is. I can't succeed at all without doing it. I did not succeed in life by intelligence. I succeeded because I have a long attention span.
4. It sounds counter-intuitive but if you want to increase discretionary time and reduce stress you need to schedule time to think. The tiny fragments of time many of us find ourselves with have a negative effect on our ability to think deeply about a problem. Furthermore they impede our ability to learn — we stay at a surface level and never move into a deep understanding. Deresiewicz warns: "You simply cannot (think) in bursts of 20 seconds at a time, constantly interrupted by Facebook messages or Twitter tweets, or fiddling with your iPod, or watching something on YouTube."
5. The opposite approach is to focus on a problem or subject and try to achieve a deep fluency. How many of us, however, have time? We don't do the work required to have an opinion. Instead we operate with surface knowledge. We tackle problems with the first thought that comes to mind. Because we make a poor initial decision, we spend countless hours attempting to correct it. No wonder we have no time to think. We're not heeding the advice of Joseph Tussman and letting the world do the work for us.
6. Listen and Apply The Following Books:

A. The Multitasking Mind By Dario Saliveci

Step 105-You Have Required To Do The Work For Writing.

1. When Give Opinion on Anything, Do Not Be so Angry and Mean to Others.
2. People Need To Stop Doing By Coming Unprepared To Give Opinion On Any Subject, Without Having Good Idea Of The Literature, and Arguments Written on Topic and Theme Available To Them. The people coming unprepared and not doing any Hard Work To Have an Opinion On The Subject or Topic. When People Coming Overconfidence, which could be resulting in Lack of Preparation, Which Could Lead That Your Position can be Destroyed with Ease. They simply won't do the work required. It's easy to come home, sit on the couch, watch TV, and zone out until bedtime rolls around. But that's not going to help you get smarter.
 - A. People Who Do Not Put The Required Work: The first thing they always do is tell you what they think. When someone has an opinion about everything, they want to share it with you. They often tout stats and research as if they had an imaginary checklist of facts they need to be able to rattle off to establish themselves as an expert in a field they actually know very little about. Because they have an opinion on everything, they are quick to judge others – for their lack of opinions, for their lack of knowledge, for their lack of outrage, and the list goes on.
 - B. People who have opinions about everything barf so much noise that it's hard to find the signal. Your brain has to work overtime to figure out if they did the work to come up with their opinions themselves or if they're simply regurgitating some oped in a newspaper. Over time, opinionated people also end up in their own prisons and they try to take you with them.
 - C. The problem comes from how we see the world. Our opinions are often rooted in how we think the world should work, according to our morals, values, and principles. If we see the world through the lens of our opinions, much of what happens will not agree with us. This is feedback, and how we respond to this feedback is key.

3. How to Get Smarter Read. A lot. Warren Buffett says, "I just sit in my office and read all day." What does that mean? He estimates that he spends 80% of his working day reading and thinking. When asked how to get smarter, Buffett once held up stacks of paper and said, "Read 500 pages like this every week. That's how knowledge builds up, like compound interest." All of us can build our knowledge, but most of us won't put in the effort. "Go to bed smarter than when you woke up."
4. How Long Does it Take To Prepare:
 - A. Depend on the topic and opponent, and how much he's written.
 - B. If the opponent nothing published, then there was very little preparation to be made because I simply didn't know what to expect.
 - C. On the other hand, if the opponent has published lots of written work and have some videos. Read and what his written and videos and prepare the summaries articles, videos, and have sense where he is coming from. This can take Weeks or Months.

5. Before Preparation. The difference between the people who do the work and the people who just reel off memorized opinions is huge. When you do the work, you can answer the next question. You know when to follow the rules and when they'll get you in trouble. When I did my postgraduate I was surrounded by people who could answer the test questions. They got good grades — actually, they got *great* grades but an odd thing happened after school: a lot of those people couldn't apply their knowledge to problems they hadn't seen before. They were chauffeurs — they knew the memorized answer. They couldn't answer the next question. We're all chauffeurs in some aspects of our lives. This is why understanding your circle of competence is so critical to living a rational life.

I. Circle of Competence:

A. **Circle Of Competence**-Understanding my Circle of Competence helps to avoid problems, identify opportunities for improvement and learn from Others. Circle of Competence is simple: Each of us, through experience or study, has built up useful knowledge on certain areas of the world. Some areas are understood by most of us, while some areas require a lot more specialty to evaluate. For example, most of us have a basic understanding of the economics of a restaurant: You rent or buy space, spend money to outfit the place and then hire employees to seat, serve, cook, and clean. (And, if you don't want to do it yourself, manage.) From there, it's a matter of generating enough traffic and setting the appropriate prices to generate a profit on the food and drinks you serve—after all of your operating expenses have been paid. Though the cuisine, atmosphere, and price points will vary by restaurant, they all have to follow the same economic formula. That basic knowledge, along with some understanding of accounting and a little bit of study, would enable one to evaluate and invest in any number of restaurants and restaurant chains, public or private. It's not all that complicated. Far more important is to honestly define what we do know and stick to those areas. Our circle of competence can be widened, but only slowly and over time. Mistakes are most often made when straying from this discipline. Where should we devote our limited time in life, to achieve the most success? So, the simple takeaway here is clear. If you want to improve your odds of success in life and business, then define the perimeter of your circle of competence, and operate inside. Over time, work to expand that circle

but never fool yourself about where it stands today, and never be afraid to say “I don’t know.”

II. Two Type of Knowledge: The Max Planck and Chauffeur Test

A. The Two Types of Knowledge: The Max Planck and Chauffeur Test: How to distinguish between the two types of knowledge: real knowledge and pretend knowledge.

- The first type of knowledge is real. It can’t be bought. It can’t be copied. If you want real knowledge you need to earn it. One is Planck knowledge, the people who really know. They’ve paid the dues, they have the aptitude. You are going to have the problem in your life of getting the responsibility into the people with the Planck knowledge and away from the people with the chauffeur knowledge. Real knowledge comes when people do the work. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- The second type of knowledge is copied. On the surface you know the answer but you lack the understanding to show your work. Then we’ve got chauffeur knowledge. They’ve learned the talk. They may have a big head of hair, they may have fine temper in the voice, they’ll make a hell of an impression. But in the end, all they have is chauffeur knowledge. I think I’ve just described practically every politician in the United States. We have the people who don’t do the work — they pretend. While they’ve learned to put on a good show, they lack understanding. They can’t answer questions that don’t rely on memorization. They can’t explain things without using jargon or vague terms. They have no idea how things interact. They can’t predict the consequences. The problem is that it’s difficult to separate the two. This is the Batesian Mimicry problem. One way to tease out the difference between Planck and chauffeur knowledge is to ask them why.
- How To Distinguish Real Knowledge and Fake Knowledge. With journalists, it is more difficult. Some have acquired true knowledge.

Often they are veteran reporters who have specialized for years in a clearly defined area. They make a serious effort to understand the complexity of a subject and to communicate it. They tend to write long articles that highlight a variety of cases and exceptions. The majority of journalists, however, fall into the category of chauffeur. They conjure up articles off the tops of their heads or, rather, from Google searches. Their texts are one-sided, short, and— often as compensation for their patchy knowledge. The same superficiality is present in business. The larger a company, the more the CEO is expected to possess “star quality.” Dedication, solemnity, and reliability are undervalued, at least at the top. Too often shareholders and business journalists seem to believe that showmanship will deliver better results, which is obviously not the case. One way to guard against this is to understand your circle of competence. Dobelli concludes with some advice worth taking to heart. Be on the lookout for chauffeur knowledge. Do not confuse the company spokesperson, the ringmaster, the newscaster, the schmoozer, the verbiage vendor, or the cliché generator with those who possess true knowledge. How do you recognize the difference? There is a clear indicator: True experts recognize the limits of what they know and what they do not know. If they find themselves outside their circle of competence, they keep quiet or simply say, “I don’t know.” This they utter unapologetically, even with a certain pride. From chauffeurs, we hear every line except this.

III. Batesian Mimicry Problem. Batesian Mimicry: Why Copycats Are Successful.

Mimic and the Real Thing:

- A. "There's two kinds of snakes you come across. There's the Texas Coral Snake, and the Mexican Milk Snake, and they both look exactly alike. The Texas Coral Snake is dangerous, it's venomous, it can kill you in a minute. The Mexican Milk Snake can't do anything to you; it's an impostor." How is it that these two look alike? It's due to a phenomenon called Batesian Mimicry.
- B. In the 1850s, the naturalist Henry Walter Bates found a certain set of butterflies who were clearly *not* of the same species but whose wings looked almost the same to the naked eye. After thinking it over, Bates eventually figured out what was going on: While the butterflies which were toxic to potential predators (the "models") were able to operate freely and relatively unmolested, there had also developed a "mimic" population of butterflies which wasn't toxic at all, yet still went untouched! In fact, biologists eventually figured out that the more toxic and dangerous the "model" was and the more frequently they appeared in the local population, the easier it was for its "mimics" to get by! Predators simply wouldn't take the risk of mixing up the two. If there aren't as many "models" around or they aren't that dangerous, the mimics have a harder time.
- C. This is a wonderful model, and in the practical world we live in, a similar phenomenon abounds: Copycats or "pretenders to the throne" are often very effective, very convincing "mimics" of the true champions. They dress the part, they talk the talk, and they know what buttons to push. But in the end, they are merely chauffeurs. We see a very Batesian effect at work: The more impressive the "model," the more effective its mimics can be in convincing people they too are impressive, and in all the same ways. But for every Warren Buffett (just one by our count), there has been many "future" Warren Buffett's. For every Steve Jobs, there have been many "next" Steve Jobs'. In fact, sometimes even just *appearances* can be quite convincing: now-disgraced Theranos founder Elizabeth Holmes was very fond of wearing a very Steve Jobsian black turtleneck outfit. Because they can be very convincing, we must be wise enough to watch out for Batesian mimicry

— even in ourselves. This brings up an interesting, at times paradoxical, question: Who can best tell the difference between a Coral Snake and its Mimics? The Coral Snake itself. The real thing knows a fake. It's worth taking the time to work on learning all the big ideas you can find, not just the ones you want to learn. In that search, you'll find a host of big winners you didn't even know existed.

6. Preparation:

- A. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it?
 - I. I have to do the reading.
 - II. I have to talk to competent people and understand their arguments.
 - III. Never try to be biased toward any of the side, but question both side of the argument.
 - IV. Do not support any side, until all the facts are put out there, clear and obvious.
 - V. Once known all the facts then analyse both sides of the argument like William Lane Craig.
 - VI. I have to think about the key variables and how they interact over time.
 - VII. I have to listen and chase down arguments that run counter to your views.
 - VIII. I have to think about how you might be fooling yourself.
 - IX. I have to see the issue from multiple perspectives.
 - X. I have to think.
 - XI. I need to become your most intelligent critic and have the intellectual honesty to kill some of your best-loved ideas.
 - XII. Be honest with yourself and open minded. ANALYSE both side of the argument logically and see which is true logically. Means has the clear terms, premises are true, and conclusion follows from premises.
 - XIII. Never say your opinion about anything that requires the analysis of the arguments and facts. Work very very hard to have an opinion about anything.
 - XIV. Listen very carefully other side and use ancient method *state the opposition argument in my own words and ask him/her if the argument I

stated in my own words represents correctly their argument and if I UNDERSTOOD Correctly their arguments.

XV. Never use cheap shots to win argument, like logical fallacies.

XVI. Debate and discussion is not about just win at any cost, but let other person to think about your arguments and engage with them. Second reason never use in discussion cheap shots toward other person, but be civil. Third reason is win the debate and discussion. Fourth is find the truth.

B. For Affirmative and Negative Case:

- I. Read, analyse, Research, Syntopicon and Investigate Published Work.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments
- II. Read Opponents Books, Articles, Newspapers, Blogs. Reading Published work. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of opponent Arguments.
- III. Watch Video. Watching Videos of the opponent. What objections he would raise against the topic and prepare the responses for each of these points.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- IV. Listen The recording that the opposition made, in which he addresses these issues.
 - Listen, Use And Apply Rules of Reading Methods Every Steps.
 - Use Grammar in Rules of Reading.
 - Use Logic In Rules of Reading.
 - Investigate Line of logic of My own Arguments.
- V. Talk with People who are students in his class, who can tell me, privately, insights into his thinking and character.
- VI. If that sounds like a lot of work, just say, “I don’t have an opinion on that; why don’t you tell me how you got to have such a firm one? It sounds like I could learn something.”
- VII. Another way to get smarter, outside of reading, is to surround yourself with people who are not afraid to challenge your ideas. “Develop into a lifelong self-learner through voracious reading; cultivate curiosity and strive to become a little wiser every day.”

7. Compound Knowledge- Are The Resources I will Choose Concentrating On the Expiring Information or Compound Knowledge?

- I. Are on the Resources providing expiring information?
 - A. Will you care about what you're reading in a month? In a year? In five years?
 - B. Are you focused enough on the same thing to build cumulative knowledge or are you too spread out?
 - C. What do you spend time on that's likely to change in the next few years? What's not likely to change?
 - D. What would need to happen for you to stop outsourcing organisation of information to the computer?
- II. Signs of The Information in the resources are expiring
 - A. First, it's marketed to you.
 - B. Second, lacking details and nuance, it's easily digestible. This is why it's commonly telling you what happened, not why it happened or under what conditions it might happen again
 - C. Third, it won't be relevant in a month or a year. Expiring information is one reason I stopped reading most news. It's a false map.
- III. While most of us focus on consuming information that we won't care about next month, let alone next year, focus on knowledge and companies that change very, very slowly or not at all. And because the information he was learning changed slowly he could compound his knowledge over time.
- IV. Doing his own thinking and vacuums up the details. When we don't think for ourselves it's easy to put the blame on someone else, to "pass the buck" so to speak.
- V. When we consume information that doesn't expire or expires slowly; is very detailed; and we spend time thinking about it not passing the buck, we can match patterns. This is how you learn to see what other people are missing. The longer you do this, the more advantage you get.
- VI. Just like the rest of us, Buffett's dependent on information and knowledge to make great decisions. Unlike most of us, he has a great memory—perhaps because he's not trying to outsource his memory or thinking to others.
- VII. A lot of what the snowball is about the concept of learning, and creating, and the advantage of having the information and knowing it. When I came here today one

of the things that I was thinking is that what you do is so much at the intersection, because retrieving information is different from having it already in your head.

VIII. What you do is different. You work on manipulating how you use the information.

In fact, Warren Buffett and Charlie Munger have the files in their head. That's why they aren't really out there googling all the time looking for, trying to look stuff up, because they already know it.

IX. I think a lot of the work that you do here is helpful to the ordinary person, but Warren Buffett or Charlie Munger don't need it. At the same time, the lesson that they have, which is that learning yourself, making yourself as smart as you can is extremely valid, and not just relying on a library where you can look something up all the time, because a lot of times when you need to make a decision, and you need 50 pieces of information, you need to know it then.

8. Proofread 10 times to see if there is a flow or grammatical or syntax mistake on my part.
9. The Art of Anticipation of Objections.
 - A. Analyse My Arguments, and Scrutinise The arguments by using Rules of Reading.
 - B. Analyse the arguments of the opponent. Scrutinise Their arguments by using Rules of Reading.
 - C. Analyse My own arguments. Scrutinise My own arguments, and the potential Loopholes in the argument by Use Rules of Reading.
 - D. Use Think, Logic, Strategem, Thinking models.
 - E. Write.
 - F. Prepare The responses to anticipated objections that, I think the opponent will bring up.
 - G. Be intellectually Prepared. This means That I need to know my arguments, so well, that nothing new can surprise me. I would also invest lots of time in knowing and know better opposite side arguments. I would read both side of the arguments, and work Hard on analysing the arguments and evidence of both sides. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey. While we all hold an opinion on almost everything. Have I do the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
 - H. Doing the work required to hold an opinion means you can argue against yourself better than others can. Only then can you say, "I can hold this view because I can't find anyone else who can argue better against my view." Great thinkers, like Charles Darwin, did the work. And it's one of the biggest reasons he's buried at Westminster Abbey.
 - I. Doing the work counteracts our natural desire to seek out only information that confirms what we believe we know. When Darwin encountered opinions or facts

that ran contrary to his ideas, he endeavored not only to listen but also not to rest until he could either argue better than his challengers or understand how the fact fit. Darwin did the work. It's wasn't easy, but that's the point.

- J. Have the best work ethic on daily basis. This is everyday process, and try to figure it out, the strengths and weaknesses of my position and opposing person position, This leads to the True Confidence.
- K. As Per Kobe Bryant statement: Trivial things should not be taken your attention. The attentions should be focused on things that is very important. Anything outside of the most important things in life, you should not have time for. You Should love the challenge in life, and always be curious, if you can be at the top , as these greats in that area. Always focus on one thing and not multiple things, this gives an edge and advantage over other people, who focusing on multiple things in life. The World Becomes a library to you, to be better at your craft.: Everything you see whether TV show I saw, Books, Journals, I read, whether discussion, debate I listen, people I talk to. Everything was done to try to learn to become better at the craft your focusing. When you have this point of view, then the world becomes your library to help you to become better at the craft.
- L. I Always need to ask myself: Have I done the work required to have an opinion on any Subject? Never allow myself to have an opinion on anything that I don't know the other side's argument better than they do. The work required to have an opinion is very hard part, have I avoid it? If that sounds like a lot of work, just say, "I don't have an opinion on that; why don't you tell me how you got to have such a firm one? It sounds like I could learn something."
- M. I might need to Suspend my judgement and tell them that I do not have an opinion on this specific Topic.
- N. Never Under Prepare, but Vastly Over Prepare for the Opponent and their arguments and responses
- O. Spend years in preparation, take debate class at the college or university. You need to participate in debates. You need to have mock debates, where someone play role of your opponent, and then you respond to them. You need to do reading and learn how to flow the debates. How to construct affirmative case and negative case. You need to take time to prepare and have enormous preparation.
- P. Memorize the arguments for my case

10. When Dialogue, Discussion, Debate Takes A Place.

A. As Affirmative Speaker, you need to present Prima Facie Case for proposition that is under debate. Prima Facie Case will be one that will establish the truth of proposition you are defending. If I am defending proposition that God Exist, I will want to give 3-5 arguments leading to that Conclusion, that God Exists, and then I will lay those out with great clarity in my opening speech, and say this is the groundwork for the debate. I am not interested in talking about other issues for example if Christianity bad for society Then, I come back to those in every speech over and over again. The goal is to make opponent argue on your grounds. You do not go over to his grounds, and let your audience forget, your affirmative case, rather you reorganise opponent speech, so that you answer his objections in so far as they reply to your arguments, so you may answer them in a very different order than he gave them, because you will be seeing for example: now what answer or response did he have to the cosmological argument, I see two basic responses and then you deal with them.

- Make Briefs, where I have suitable objection, and then have two or three responses to those objections.
- Use The Brief During Exchange with the Opponent. File these Briefs into Folders, and spread These Manila Folders out in front of me on Desk, When I am interacting with the Opponent. Once the opponent Rises his point I just pull These briefs from these folders and never have to think on my feet because I am completely prepared. Key is never have to think on the feet to be so well prepared, that I would have my responses ready for anything he brings up.
- Quote Peer Review Scientific Articles on the topic in support the conclusions.

B. Take Notes While the Opposition is speaking:

- How To Take Notes- Flow Chart. By Taking Notes, I am sure that I am responding to my opponent's arguments and everything he brings up.

- I. Make 11-12 Columns on the Pad. Prepare the left column in advance of the communication, debate. The Left Column needs to be filled in, if you starting first. If not, then leave left column as blank.
- II. First Left Hand Column Are My Arguments.
- III. Second Left Hand Column are Opposition Arguments and Responses to My arguments.
- IV. Third Left Column are My Responses to the Opponent responses.
- V. Fourth Left Hand Column are My Rebuttal.
- VI. Fifth Left Hand Column are Opponent Rebuttal.
- VII. Sixth Left Hand Column are my Responses to the Opponent rebuttal.
- VIII. Seventh Left Hand Column is the Final My Rebuttal.
- IX. Eight Left Hand Column is The opponent Rebuttal.
- X. Ninth Left Hand Column is my closing statements.
- XI. Tenth Left Hand Column is the opponent closing statements.
- XII. Eleventh Left Hand Column is the Cross Examination.
 - My Answer.
 - Opponent Answer.
 - My response to the response of the opponent.

C. Always Remind the audience what are your three to five arguments and what are the responses of the opponent, if any to your arguments.

D. Always allow the opponent allow to lay out his argument without interruption.

E. Take the opponent arguments and put in my own words and correctly represent their argument carefully without misrepresentation.

F. Proofread 10 times to see if there is a flow or grammatical or syntax mistake on my part.

G. Be Honest.

H. Be Open Minded.

I. Always from Your side be honest and rigorous exchange of arguments and counter Arguments from which me and opponent would benefit.

- J. One of good technique is whenever you can quote an opponent against himself, this is powerful device. Have the manuscript, point to the footnote, cite the book, and the quotation and have the page number.
- K. Never Take Cheap Shots at the Opponent.
- L. Encourage not just trust someone say so, but demand published peer reviewed articles in support of the positions that one take
- M. Always look at the reality of the situation, and do not let the emotion cloud the situation and the execution. Always be in the present and the moment.

Step 106-Use Rules of Reading for Writing

1. Listen, Follow and Apply Rules of Reading of Bible Study, Deep Work, Deep Study, Analysis, Syntopicon and Research ON the Topic Before Any Writing On The Subject.

A. VERY VERY FAST Reading- Skimming. Pages 47-51.

B. VERY FAST READING- Entertainment.

I. Method 1-Speed Reading. FAST Reading. Pages 59-64.

C. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.

I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.

II. Method 2-Use 80/20 Principle For Reading. Pages 68.

III. Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.

IV. Method 4-Flip Through Pages and Analyse. Page 70.

V. Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.

VI. Method 6-Devotional Bible Read. Pages 73-74.

D. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- I. Method 1-Chapter Summary Method. Pages 143-147.**
- II. Method 2-Character Quality Method. Pages 148-160.**
- III. Method 3-Thematic Method. Pages 161-163.**
- IV. Method 4-Biographical Method. Pages 164-176.**
- V. Method 5-Topical Method. Pages 177-180.**
- VI. Method 6-Word Study Method. Pages 181-189.**
- VII. Method 7-Book Background Method. Pages 190-194.**
- VIII. Method 8-Book Survey Method. Pages 195-205.**
- IX. Method 9-Chapter Analysis Method. Pages 206-215.**
- X. Method 10-Paragraph Study. Pages 216-229.**
- XI. Method 11-Verse by Verse Analysis Method. Pages 230-234.**
- XII. Method 12-Book Synthesis Method. Pages 235-238.**
- XIII. Method 13-Theological Study Method of Bible Study. Pages 239-245.**
- XIV. Method 14-Studying Bible Prophecy. Pages 246-259.**
- XV. Method 15-Typological Study Method. Pages 260-262.**
- XVI. Method 16- John MacArthur Way Bible Study. Pages 263-268.**
- XVII. Method 17-Inductive Bible Study Method. Pages 269-296.**
- XVIII. Method 18-BIBLICAL HERMENEUTICS. Pages 297-302.**
- XIX. Method 19-Theological Group of Principles. Pages 303-306.**
- XX. Method 20- How To Read A Book Pages 307.**

E. VERY VERY SLOW READING- COMPLEX TEXT. Deep Work, Shallow Work, Bible Study, Analysis of Text, Research, Investigative Journalism, Investigation and Syntopicon, Mixed Method.

- I. Method 21- How To Read A Book By Mortimer Adler Various edition Pages 341.**
- II. Method 22-How To Read A Book For Various Books. Pages 342-600.**
- III. Method 23- Syntopicon Pages 601-642.**
- IV. Method 24-The Craft of Research. Pages 644-882.**
- V. Method 25-Research Books can Be Used. Pages 883-897.**
- VI. Method 26-Investigative Journalism. Pages 898-923.**
- VII. Method 27-Mixed Methods of Rules of Reading. Pages 924-942.**

2. Apply The Books On Writing

Step 107-Books On Writing

1. **Listen, Follow And Apply Rules of Reading Part 1 to 13, before looking into Writing.**
2. **Listen, Follow and Apply the following Books For Writing.**
 - A. **Writing Research.**
 - I. **How to Read A Book By Mortimer Adler Various Editions**
 - II. **How-to-Write-a-Better-Thesis.**
 - III. **A Manual for Writers of Research Papers, Theses, and Dissertations.**
 - IV. **Academic writing_ A Handbook for International Students.**
 - V. **Authoring a PhD How to plan, draft, write and finish a doctoral thesis or dissertation.**
 - VI. **English for Writing Research Papers.**
 - VII. **How to Write and Publish a Scientific Paper.**
 - VIII. **How to Write Better Medical Papers.**
 - IX. **How to write dissertations & project reports.**
 - X. **Little Brown Handbook, The, MLA Update Edition.**
 - XI. **Mastering Academic Writing in the Sciences _ A Step-by-Step Guide.**
 - XII. **Patterns for College Writing_ A Rhetorical Reader and Guide.**
 - XIII. **Patterns for College Writing, Brief Edition_ A Rhetorical Reader and Guide.**
 - XIV. **Planning Your Research and How to Write It.**
 - XV. **Steps+to+Writing+Well.**
 - XVI. **The Craft of Scientific Writing.**
 - XVII. **Writing Science_ How to Write Papers That Get Cited and Proposals That Get Funded.**
 - XVIII. **Writing Scientific Research Articles_ Strategy and Steps.**
 - XIX. **The Longman Writer_ Rhetoric, Reader, Research Guide, and Handbook.**

B. Writing Novel.

- I. Compact Literature_ Reading, Reacting, Writing, 2016 MLA.**
- II. The Complete Handbook of Novel Writing_ Everything You Need to Know to Create & Sell Your Work.**

C. Writing Children Book.

- I. How to Write a Children's Book and Get It Published.**

D. Writing Legal Writing.

- I. Legal Writing and Analysis.**

E. Writing Fiction.

- I. An introduction to literature _ fiction, poetry, and drama.**
- II. Classic Writings on Poetry.**
- III. Compact Literature_ Reading, Reacting, Writing, 2016 MLA.**
- IV. How to Write Poetry_ And Get it Published.**
- V. Literature and the Writing Process.**
- VI. Popular Lyric Writing_ 10 Steps to Effective Storytelling.**
- VII. Writing Poetry.**
- VIII. How to Write Like Tolstoy_ A Journey into the Minds of Our Greatest Writers.**

F. Writing Non-Fiction.

- I. Compact Literature_ Reading, Reacting, Writing, 2016 MLA.**
- II. On Writing Well, The Classic Guide to Writing.**
- III. Executive Writing Skills for Managers_ Master Word Power to Lead Your Teams, Make Strategic Links and Develop Relationships.**
- IV. The Sense of Style_ The Thinking Person's Guide to Writing in the 21st Century .**

G. Writing Technical Writing.

- I. Technical Writing 101_ A Real-World Guide to Planning and Writing Technical Documentation.**
- II. The Blackwell Encyclopedia of Writing.**
- III. The Handbook of Technical Writing.**
- IV. Writing With Power Techniques for Mastering the Writing Process.**

H. Writing Comedy.

Step 108-How To Become Straight A Student

Efficiency. The simple truth is that the brute force techniques used by most students are incredibly inefficient. When it comes to exam preparation, passive review is not an effective way to learn complicated concepts. It's also mentally draining, which further diminishes the rate at which you can absorb and internalize information. For paper writing, this same problem holds. When you approach the task without proper preparation, it becomes incredibly tiring and you can end up spinning your wheels. After a while, even the formation of coherent sentences becomes difficult and time intensive. In contrast, the techniques I came up with were so streamlined that I could learn more material than my classmates and actually spend less time studying. By eliminating stupid habits and wasted effort, I transformed exam prep and paper writing from a dreaded chore to a targeted activity. You will learn how to:

- Manage your time and deal with the urge to procrastinate.
- Take targeted notes in class.
- Handle reading assignments and problem sets with ease.
- Prepare efficiently for exams.
- Master the art of exam-taking.
- Write incisive critical analysis essays.
- Conduct thorough research.
- Write standout term papers.

A big part of the solution is timing—they gain efficiency by compressing work into focused bursts. To understand the power of this approach, consider the following simple formula:

work accomplished = time spent x intensity of focus

With this formula in mind, you can begin to understand why many straight-A students actually study less than their classmates: They replace long, low-intensity stretches of work with a small number of short, high intensity sessions. Of course, this is not the whole story behind their success; what straight-A students actually do in these short bursts is also crucial—technique is just as important as timing. Part Two (Quizzes and Exams) and Part Three (Essays and Papers) of this book are dedicated to these technical details. But learning how to follow an efficient schedule, and banishing pseudo-work from your college experience for good, is a crucial first step toward your academic overhaul.

Quizzes vs. Exams

If the test is worth less than 15 percent of your final grade, it's a quiz; otherwise, it's an exam. If the test is worth only 5 percent or less of your grade, designate this a tiny quiz. Don't spend too much time on tiny quizzes. Even if you fail one, it still probably won't change your final letter grade. And if you're attending classes and keeping up with your reading, you should be able to score above average with little to no preparation.

Step 1

Take Smart Notes

Gather the Right Materials When I was a freshman, less than half of my class brought a laptop to campus. The year I graduated, over 95 percent of incoming freshmen brought laptops. By the time you read this, laptops will more or less be the de facto standard for undergraduates across the country, and this is a great advancement for the cause of collegiate note-taking. Why? I think David, another Dartmouth student, put it best: "Use your laptop. Seriously! You will be overwhelmed by the quality and legibility of your notes... it's really a no-brainer."

Take Smart Notes in Nontechnical Courses (What's the Big Idea?)

The key to doing well in these courses is straightforward: Identify the big ideas. That's what it all comes down to. Exams in nontechnical courses focus entirely on big ideas—they require you to explain them, contrast them, and reevaluate them in the light of new evidence. If you are aware of, and understand, all of the big ideas presented in the course, these tasks are not so difficult, and strong grades will follow. As you would expect, lectures are a major source of these big ideas. Identifying them, however, is not a trivial task.

Professors ramble. And they rarely start a class by clearly identifying the big ideas that will be explored. Instead, they tend to dive right in, leaving the poor student to separate on his own the interesting conclusions from the digressions.

Format Your Notes Aggressively

When it comes to formatting the text itself, the basic rule to follow is that anything that makes the information easier to read is fair game. You don't need a consistent scheme. Don't be afraid to use aggressive text formatting to help emphasize important points. On a computer, smart students often make use of bold fonts and lists to help organize their thoughts. Capture Big Ideas by Using the Question/Evidence/Conclusion Structure Keep in mind that professors don't always state the question. Often they jump right into the evidence and leave it to you to deduce the question being discussed. Don't be afraid to jot down "QUESTION:" and then leave the rest of the line blank as you begin recording evidence. Once you figure out what the professor's talking about, you can go back and fill in this blank.

The same holds true for conclusions. Professors will sometimes hint at a conclusion but not come right out and present a neat endpoint for the current discussion. In this case, it will be up to you to synthesize the question, evidence, and professor's hints into a conclusion of your own. This is the important part. When you formulate a conclusion, you are cementing a big idea. If you can't finalize a conclusion before the professor moves on to the next question, simply jot down "CONCLUSION:" and plan to come back later during a lull in the lecture, or immediately following class, to fill in the blank.

Step 2

Demote Your Assignments

Work Constantly

Most college students depend on “day-before” assignment planning, meaning they never start an assignment until the day before it’s due. This might be the simplest scheduling decision, but it creates many problems. Large assignments will quickly transform from potentially interesting to tedious to painful when tackled in one monolithic, last-minute chunk of time. And, if two or more assignments happen to be due on the same day (which will happen often), you will be forced into a frenzied work marathon that will produce lackluster results at best. Smart students avoid these issues by working constantly on assignments, in small chunks, every day. “I try to sit down every Sunday night and plan out the week,” explains Simon, a straight-A student from Brown. “My goal is to make sure that I don’t have too much work on busy days and that I do at least a little bit each day.” For example, if you have a problem set due every week, complete one problem a day, one hour at a time. Don’t spend five hours the night before. The same goes for reading assignments—knock off a chapter a day, and you’ll never find yourself spending a lonely night with a textbook and a six-pack of Red Bull.

Bear in mind that even if you get caught up on all of your assignments for a given class, you should continue to work. For example, if it’s Sunday morning and you have already finished your reading for Monday’s history class, and you have time to spare, break out a book and do a little of the reading for Wednesday’s history class. This doesn’t mean that you should study like crazy twenty-four hours a day. Don’t stay up until 2 A.M. Sunday night trying to finish the entire week’s load. But on days where you happen to be ahead of schedule, and you have already put aside time to work on a certain class, take advantage of this fortuitous situation to get ahead. Once you get used to working a little bit every day, you’ll be surprised by how often this situation might arise.

Don't Read Everything

For example, in most college courses there are one or two sources that show up on the reading list for almost every lecture. We will call these favored sources— they're usually a textbook or a course reader, and they provide the basic structure for the course by outlining key facts and arguments in a condensed form. Always read the assignments from favored sources.

Professors usually augment these favored sources with a variety of supplemental readings that provide context or analyze certain arguments and events in more detail. These supplemental readings are often academic papers, transcripts of speeches, or chapters from books —and they are typically fascinating. But they are also typically expendable, and you should not plan on reading them all. Instead, if your time is limited during a particular week, then your strategy should be to select only the most important supplemental readings for review. So how do you decide which supplemental readings to review, which to skim, and which to skip? Straight-A students follow this simple hierarchy: Readings that make an argument are more important than readings that describe an event or person, which are more important than readings that only provide context (i.e., speech transcripts, press clippings).

Confirming Your Decisions

You should always use the lecture itself to confirm your choice about what to read and what to skip. If the professor emphasizes the importance of a work that you dismissed (which will happen occasionally—this system isn't perfect), then make a note that you will need to go back and cover this reading in more detail before the next exam. A smart technique is to simply write these skipped readings right onto your syllabus as an assignment for a later class. Choose a day with a light reading load, and treat the assignment as if it was given to you by your professor. If you don't explicitly schedule a time to cover this material, you will invariably procrastinate and then find yourself with a huge reading list to cover right before the exam.

Take Smart Notes on Your Favored

Reading Assignments

We've discussed which readings to ignore or skim. But the logical next question is what to do with the favored sources that you decide to read carefully. In this situation, how you take notes on the reading makes a big difference. If you write down very little, the assignment can be completed fast, but the time will be wasted because you won't have bothered to extract the big ideas in a way that makes them accessible when it comes time to study. If, on the other hand, you take detailed notes on every paragraph, your assignments will take way too long to complete. The best compromise is to use a strategy similar to the one outlined earlier for taking lecture notes. To refresh your memory, the core of this strategy is that all big ideas can be reduced to a question, evidence, and conclusion. This approach can work wonderfully for reading assignments as well. Apply it as follows:

First, as with lectures, try to take notes on your computer. They will be more organized and easier to computer. They will be more organized and easier to follow later on, when you use them for review. In addition, typing makes it easier to record more and finish faster. Next, carefully read the beginning of the assignment. Look for the question being answered by the author. Note that this is different than a thesis statement. For example, "Why did the Clinton health care plan fail?" is a question. "The Clinton health care plan failed because of resistance from commercial health care providers" is a thesis. In a reading assignment, the question can usually be found in the title or perhaps explained in the first few sentences. Record this in your notes, and label it clearly. Next, look for the

author's conclusion (the thesis statement). This is perhaps the most difficult part, since academics are known to propose complicated answers to their questions, especially when writing. So it may take some serious consideration to figure out what's being suggested. Search the first few paragraphs; this is typically where the conclusion is hidden. Also check the final few paragraphs. Often a thesis is proposed at the beginning of an article but then refined slightly at the end once all of the supporting evidence has been presented. When you feel confident in your understanding of the conclusion, record it carefully in your notes. Don't worry if it takes several sentences to capture the point—err on the side of being thorough. Now comes the easy part: Skim the entire reading. Now comes the easy part: Skim the entire reading. Don't take notes yet. Instead, use a pencil to make checkmarks next to important paragraphs that jump out at you. Because you are reading fast, you may miss some points—don't worry. "Just get the gist of the author's message and how he is supporting that message with evidence, then move on," explains Jason, a straight-A student from the University of Pennsylvania. You don't need to capture everything. Your goal is simply to mark a few solid examples that justify the conclusion as the answer to the question. Once you have skimmed through the entire reading, go back and find your check marks. For each mark, record in your notes a concise summary of the corresponding point. Label each point in your notes with the page number where you found it. This shouldn't take long. Don't worry about being formal or grammatically correct. Just dump these pieces of evidence into your notes. When you're done, your notes should contain a clearly labeled question followed by a half-dozen or so bullet-pointed pieces of evidence, then a clearly labeled conclusion.

Don't Work Alone on Problem Sets

Perhaps the most important rule for taming the problem sets assigned in technical courses is to follow our earlier rule and work on them constantly. As Ryan, a straight-A student from Dartmouth, explains: “You can work on problem sets in small pieces while you’re between classes or activities.” Concentrating on only one or two problems a day will help you avoid mental fatigue. Once your brain gets tired, it’s easy to stall—but if you spread out your work, you will end up spending fewer hours on the assignment than if you tried to do it all at once.

Even with a smart schedule, however, you will probably still get stuck occasionally. When this happens, use all the available resources to help you get unstuck. If you’re allowed to collaborate with your classmates, which is often the case in technical courses, definitely take advantage of this opportunity. As Greta from Dartmouth explains, working in groups “can drastically cut the time required to finish a really hard problem set.” Identify one or two students who share a similar skill level. Identify one or two students who share a similar skill level as you and then construct a regular schedule for working together on the class assignments. Set your meeting dates for two or three days before the deadlines; this gives you time to first try the problems on your own and identify the ones that give you the most trouble. Then, when you meet with your problem set group, your energy will be focused where it’s needed most. However, don’t meet the day before your deadline. It’s important to have at least one day before handing in the assignment so you can review all of your answers and fix any small mistakes. You should also take advantage of office hours. Most technical courses hold office hours once a week, usually run by a teaching assistant (TA). These meetings are meant to clarify complicated concepts from class and to be a source of help on hard problems. Always go to office hours, if you have time, and arrive knowing which homework problems pose the biggest challenge to you. Don’t be afraid to ask for help. You will learn a lot during these weekly sessions, since the TAs will be able to walk you through the more difficult concepts—which will ultimately save you a lot of time and frustration.

Solve Problems on the Go

First, set aside a little block of time to familiarize yourself with a couple of problems, and make sure you understand exactly what is being asked. You may need to review your notes to refamiliarize yourself with the relevant concepts. Next, try to solve the problem in the most obvious way possible. This, of course, probably won't work, because most difficult problems are tricky by nature. By failing in this initial approach, however, you will have at least this initial approach, however, you will have at least identified what makes this problem hard. Now you are ready to try to come up with a real solution. The next step is counterintuitive. After you've primed the problem, put away your notes and move on to something else. Instead of trying to force a solution, think about the problem in between other activities. As you walk across campus, wait in line at the dining hall, or take a shower, bring up the problem in your head and start thinking through solutions. You might even want to go on a quiet hike or long car ride dedicated entirely to mulling over the question at hand.

Write Solutions Right the First Time

Another important time-saving tip for problem set work is to record solutions formally the first time you write them down. Many students first jot down their answers informally and then return later to reformat them into something neat enough for submission. There is no reason to include both steps. You are, for no good reason, adding a lot of extra time to the process. Instead, go slowly and deliberately the first time. Write your answer carefully, and clean it up immediately until it is of submission quality. Then you can cross the assignment off your list and it will be one less thing to worry about.

Step 3

Marshal Your Resources

Smart students understand that if you're studying hard, then you've done something wrong. Preparing for a test should not be painful. And it should not require a lot of time. If you have been putting Steps #1 and #2 into practice, taking smart notes and handling assignments effectively, studying should not be a big deal for you either. In fact, when faced with a looming quiz or exam, you have to do only two things. First, organize your material intelligently. Second, perform a targeted review of this material. This section will teach you how to accomplish the former. Don't worry—organizing your material properly is not a difficult task, but it is important that you do it right. Many students neglect this step, eager to dive right into the review, but by doing so they condemn themselves to hours of unnecessary work. You don't want to be like these students. Pay attention to the advice that follows and you will experience a significant reduction to the difficulty of your study experience.

Define the Challenge

Before you can conduct any meaningful studying, you must first define the scope of the exam. As Simon from Brown puts it: "You need to know what kind of information the professor wants you to know." To accomplish this goal, answer the following questions:

- Which lectures and reading assignments (or problem sets) are fair game?
- What type of questions will there be, and how many of each? As Christine from Harvard explains: "It's helpful to know in advance what kind of knowledge will be asked for on the exam—IDs, dates, broad syntheses of the texts' major arguments?"
- Is the exam open note or open book?
- For a technical class, will formulas be provided or do they need to be memorized?
- How much time will be available? Does the professor expect the exam to be easy to complete during the test period or a challenge?

Some professors offer answers to these questions without being prompted. Many, however, do not. If it's two weeks before the exam, and the professor hasn't mentioned any details yet, you should ask. If you're shy, ask after class. But get the information as early as possible—it's crucial to your success. Build a Study Guide (Organizing Nontechnical Course Material) "I have always been a big fan of making a study guide," admits Ryan from Dartmouth. This is a technique that popped up again and again in my

straight-A interviews. Each student, of course, had his or her own variation on study guide creation, but they all followed, more or less, this same general approach:

For a nontechnical course, once you find out which lectures and reading assignments are fair game for the exam, print out the corresponding notes that you've typed up or gather the pages you've written on (don't be afraid to deconstruct your notebook). Cluster these pages into piles, separated by general topic. Clearly label each of these piles with its topic and fasten them together with a paper clip so you can easily transport them without mixing up the pages. This final step is important, since you will be moving to and from your various isolated study spaces once you begin your review. For simplicity, we will refer to these topic-themed piles as "chapters." Your final study guide, therefore, should contain a chapter, consisting of reading and lecture notes, for each general topic that might be covered on the exam.

Construct a Mega-Problem Set (Organizing Technical Course Material)

For a technical course, many students follow a variant of the study guide approach that focuses on sample problems. It works as follows: Your problem set assignments are the key to your review process. Start a pile for each problem set that covers material that might appear on the exam. Next, you'll need to supplement each problem set with sample problems from your lecture notes. For each lecture relevant to the upcoming exam, do the following:

1. Match the lecture to the problem set that covers the same material.
2. Copy sample problems from these lecture notes onto a blank sheet of paper. You don't have to copy the steps or the answers, just the questions.
3. Label the blank sheet of paper with the date of the lecture. This will help you later figure out where these problems came from (and more important, where their answers can be found).
4. Fasten this sheet with a paper clip to the problem set you matched it to in step one. In other words, this process transforms your problem sets into mega-problem sets by adding extra problems drawn from your lecture notes. Pretty simple.

Finally, you must augment your mega-problem sets with technical explanation questions. What are these?

For every major topic covered in a particular megaproblem set, jot down a question that asks you to explain the basics of the topic. For example, as Greta from Dartmouth recounts, in an “economics course, I would make study sheets and then add a general question such as: what happens when a government increases spending and lowers interest rates?” Or, for a chemistry class, you might have a problem set containing many questions that require you to draw the molecular structure of specific chemical compounds. In this case, you could add a technical explanation question along the lines of: “Explain the general procedure for drawing a molecular structure, why this is useful, and what special cases must be kept in mind.” It’s important that you add these technical explanation questions in addition to your regular sample problems, since they will reveal whether or not you understand the underlying concepts or if you’ve just memorized the steps for some particular problems. One last note: If your professor makes a practice exam available, then print out a copy of it and store it with your mega-problem sets. For technical courses, sample exams are a great review tool, and you will definitely want to have them handy when it comes time to study.

Prepare Memorization Aids

Both technical and nontechnical courses sometimes require you to do some memorization—formulas, chemical equations, artwork, dates, or chronologies—and the most efficient way to memorize this information is by using flash cards. Almost every straight-A student interviewed for this book used flash cards to help with rote memorization. Fortunately, this technique is easy. Buy a stack of index cards, put the prompt on one side and the answer on the other. Constructing these flash cards, however, can take longer than you might imagine, so start early. If possible, start writing up your cards at least a week before the first day you plan to actually study. The activity is mindless—you can write flash cards while watching TV—so it shouldn’t be too hard to get them done, in advance, bit by bit.

Schedule Your Organization Wisely

Don't try to organize and study in the same day. This is a crucial tactic used by many straight-A students. When you review, you want your brain at full power. If you organize your materials the same day that you review them, your brain will be too tired to accomplish both effectively. So keep these two tasks separate and you'll end up working more effectively, which reduces the total time spent and produces better results.

Step 4 Conquer the Material

This is the step students most commonly identify with exam preparation. It's also the step that most students misguidedly spend the majority of their time on. You're not most students—at least not anymore. All of the work you put in up to this point was meant to make this one step as small and painless and insignificant as possible. So don't worry. There are no all-nighters in your future. What follows are powerful techniques for taking your imposing piles of study material and imprinting the key ideas on your mind as efficiently as possible. These techniques are quick but ruthlessly effective. Use them with confidence. They get the job done, and they get it done fast.

USE Feynman Technique

Feynman Technique

- I. **Choose a Concept, Idea, topic to Learn. Select a Topic You are interested in learning about and write it at the top of the blank page in the Notebook or Paper.**
 - A. Choose your topics carefully: Not everything that you study suits this technique. Usually abstract complex ideas are best understood by Feynman technique but ideas that are evidence-based/observational might not really be suited for this.
 - B. Selecting a concept to study compels you to be intentional about what you don't know. It also forces you to choose a topic that's small enough that it could reasonably fit onto one or several pages.
 - C. **You face what you don't know.** By writing a topic down on a blank page, you acknowledge you're starting from scratch or at least filling in some blanks. In doing so, take the initial step in the process.
 - D. **You need to be specific.** Given the accumulated knowledge in the universe, most of us know nothing about most things! Writing down explicitly what you don't know provides you with a starting point.
- II. **Use It For Real.**
 - A. Use it for real: perfectly suitable for weekly tech-talks, lectures, paper-reading, Study, Bible Study, Sermon or any type of study, deep work and deep study sessions.

III. Study The Topic By Reading, Listening, Watching and Communicating.

- A. You have to start small. You really only have a page (or a few) to fill up with information. You can't fit everything there is to know about "Evolutionary Science" or "Microeconomics" or "Psychology" on a page. Instead work on smaller more defined concepts or what might reliably be found on a midterm or final exam.
- B. Fully understand the complex topic first: Don't begin the learning process by explaining it before you actually understand it. Retention methods such as Feynman technique, active-recall and spaced repetition are for solidifying information that you already understand. Trying to solidify an information before you understand it might end up encoding wrong interpretation of a topic.
- C. Actually put the time and effort: Once you have selected the correct set of topics, make sure you actually spend the time and effort to go through the entirety of the techniques. Feynman technique is great for having a basic framework of the topic inside your head with the details chopped off. It's important to get a very clear picture of the basics in your head right - the details can be filled in later.
- D. Make it your own.
 - Start with not knowing.
 - Ask 'why?'. ask why $x=y$. or why does music has 12 notes and not 14.
 - Study the story of what you are studying. E.g. study what was physics before Quantum theory. Why QT was needed, who were the people involved in developing the QT and how it changed the world.
- E. Take Notes On the Topic From Study.
- F. Consolidate the information concisely onto a flashcard or some other place for long term retention: Once we really understand a topic to be able to explain the core principles without having to use jargon, we should hold onto that understanding. Unfortunately, a large portion of that information that we just gathered is lost within first 48 hours after learning. So note it down somewhere before you lose it. Optimise for spaced-repetition for next sessions.
- G. Don't write notes on notes: Life is short.
- H. Cornell Notes.
 - How Will I Take Notes and Cornell Note Take Method Pages 79-82.

IV. Simplify The Topic For Myself First.

- A. Simplify your explanation so that YOU understand it. As long as the explanation is not simple enough for YOU to understand, spend more hours to break it down to basic, bare-bone, core ideas.
- B. Avoid jargon and complexity. The simpler the explanation, the more likely you are to remember it.
- C. Only Use Simple Words. The words a child would understand.
- D. Anyone can make a subject complicated but only someone who understands can make it simple. Jargon hides our lack of understanding. When forced to write out an idea from start to finish in simple language, you discover where you struggle, where it doesn't quite make sense, where you get frustrated, where you don't really understand as well as you thought. Only by identifying gaps in your knowledge can you fill them.
- E. But true understanding requires a more active process like *teaching*. Start out by formally teaching yourself. Write out a summary in your own words without looking at your notes. Or explain it to yourself out loud. Then take it to the next level by teaching other people. Teaching also initiates a feedback loop, where critique or questions can help us learn and sharpen our thinking.
- F. **It makes it harder to trick yourself.** When you have to truly explain something, whether through writing or aloud, you encounter the holes in your reasoning and the white spaces in your knowledge. Think of writing and teaching as a process to *obtain understanding*, not something you do once you already understand.

V. Reflect, Refine, and Simplify

- A. Only when you can explain the subject in simple terms do you understand it.
- B. Simple is beautiful.
- C. Review your notes to make sure you didn't mistakenly borrow any jargon or gloss over anything complicated.
- D. Read it out loud as if to a child. If the explanation isn't simple enough or sounds confusing, that's a good indication that you need to reflect and refine.
- E. Go back to the source material, reviewing the parts you don't quite understand yet.
- F. Repeat until you have a simple explanation.

VI. Return to the source material if you get stuck. Go back to whatever you're learning from – a book, lecture notes, Journal, Newspaper, podcast or any other resource and source – and fill the gaps in your knowledge.

A. Step 1- Use The Chosen Rules of Reading Method For Analysis, Syntopicon, Research, Investigative Journalism or Mixed Method and Follow Each Steps Of The Method Until Finish All Steps, While Re-listen Lectures, Read Books or Lecture Notes 1-100 Times For Each Step.

B. Step 2- Following Rules of Reading Methods:

C. VERY VERY FAST Reading- Skimming. Pages 47-51.

D. VERY FAST READING- Entertainment.

I. Method 1-Speed Reading. FAST Reading. Pages 59-64.

E. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.

I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.

II. Method 2-Use 80/20 Principle For Reading. Pages 68.

III. Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.

IV. Method 4-Flip Through Pages and Analyse. Page 70.

V. Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.

VI. Method 6-Devotional Bible Read. Pages 73-74.

F. Deep Work, Deep Study, Bible Study or Any Book- SLOW Reading- Complex Text.

- A. Learning should be iterative. More often than not, learning something challenging takes several attempts. With the Feynman Technique, returning to the source material is an explicit part of the learning process. When gaps in our knowledge arise and our explanations aren't quite right, revisiting our primary and secondary sources can help solidify what we're learning.
- B. Getting it right will likely take several iterations. That's a good thing; the more you refine your explanations, the more your understanding will deepen. Learning becomes an iterative process. Rather than viewing learning as one-and-done, this step gives you permission to continuously refresh your knowledge.
- C. You're actively engaged. Using sources to polish our own explanations and models is an active process. When we learn passively, committing details to memory is more challenging. When we're actively part of creating our own summaries and reasoning, drawing intentionally from original information to fill our blind spots, we can more readily commit knowledge to our long-term memory.
- D. You expand your knowledge base. Paradoxically, the more we learn, the more *our capacity* to learn increases. Looking through a chapter of a textbook might feel like a different language the first time around. The second time it becomes more clear. The third time, with a strong base already, we pick up nuances we couldn't have possibly seen before.

VIII. Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious. Additionally, think of analogies that feel intuitive.

- A. Every field of study has its own specialised terms. While it may be important to know them, it's also important to not confuse knowing jargon with knowing concepts. The Feynman Technique involves simplifying our initial explanations and refining our understanding through simple analogies..Why this step works:
- B. Simplicity is a proxy for understanding. It's easy enough to commit terms to memory, and repeat them back when prompted. But memorisation is not understanding. When we can't rely on big words that make us sound smart, we have to distill what we truly know to the most basic form. This is where true understanding takes place.
- C. Analogies are easier to recall and explain. When you understand a challenging concept, analogies allow you to create a short-hand for recalling it quickly and explaining it to others clearly. Learning material often provides ready-made analogies for us. For example, we all probably have "the mitochondria are the powerhouse of the cell" burned into our collective memories. However, pushing ourselves to create our own analogies is even more powerful than regurgitating a borrowed one that we may not actually understand.

IX. Teach it to yourself or someone else. Write everything you know about a topic out as if you were explaining it to yourself. Alternately, actually teach it to someone else.

- A. Classic learning mistake is reading an article or textbook and considering our learning complete. In reality, reading is not understanding. We might even take notes, essentially transcribing a resource's sentences into our notebooks. We often nod to ourselves, thinking we've grasped a subject. After all, *we've taken notes*.
- B. Remove any jargon or complexity.
- C. Only Use Simple Words. The words a child would understand.
- D. Anyone can make a subject complicated but only someone who understands can make it simple. Jargon hides our lack of understanding. When forced to write out an idea from start to finish in simple language, you discover where you struggle ... where it doesn't quite make sense ... where you get frustrated ... where you don't really understand as well as you thought. Only by identifying gaps in your knowledge can you fill them.
- E. But true understanding requires a more active process like *teaching*. Start out by formally teaching yourself. Write out a summary in your own words without looking at your notes. Or explain it to yourself out loud. Then take it to the next level by teaching other people. Teaching also initiates a feedback loop, where critique or questions can help us learn and sharpen our thinking.
- F. **It makes it harder to trick yourself.** When you have to truly explain something, whether through writing or aloud, you encounter the holes in your reasoning and the white spaces in your knowledge. Think of writing and teaching as a process to *obtain understanding*, not something you do once you already understand.
- G. **It's even harder to trick others.** If an explanation you're providing doesn't make sense, they'll often tell you or you can pick up cues like blank stares. As a test, ask them to repeat what you taught them in their own words. If they can't do this, your explanation is too complex — simplify it and use plain language.
- H. **You build confidence.** When you truly understand something, it clicks. You can explain it forward and backwards, pointing out exceptions and spotting logical inconsistencies. When this happens, it builds confidence and pushes

you to tackle even more challenging subjects knowing you have a solid framework for learning.

X. Reflect, Refine, and Simplify.

- A. Only when you can explain the subject in simple terms do you understand it.**
- B. Simple is beautiful.**
- C. Review your notes to make sure you didn't mistakenly borrow any jargon or gloss over anything complicated.**
- D. Read it out loud as if to a child. If the explanation isn't simple enough or sounds confusing, that's a good indication that you need to reflect and refine.**
- E. Go back to the source material, reviewing the parts you don't quite understand yet.**
- F. Repeat until you have a simple explanation.**

XI. Return to the source material if you get stuck. Go back to whatever you're learning from – a book, lecture notes, Journal, Newspaper, podcast or any other resource and source – and fill the gaps in your knowledge.

- H. Learning should be iterative. More often than not, learning something challenging takes several attempts. With the Feynman Technique, returning to the source material is an explicit part of the learning process. When gaps in our knowledge arise and our explanations aren't quite right, revisiting our primary and secondary sources can help solidify what we're learning.
- I. Getting it right will likely take several iterations. That's a good thing; the more you refine your explanations, the more your understanding will deepen. Learning becomes an iterative process. Rather than viewing learning as one-and-done, this step gives you permission to continuously refresh your knowledge.
- J. You're actively engaged. Using sources to polish our own explanations and models is an active process. When we learn passively, committing details to memory is more challenging. When we're actively part of creating our own summaries and reasoning, drawing intentionally from original information to fill our blind spots, we can more readily commit knowledge to our long-term memory.
- K. You expand your knowledge base. Paradoxically, the more we learn, the more *our capacity* to learn increases. Looking through a chapter of a textbook might feel like a different language the first time around. The second time it becomes more clear. The third time, with a strong base already, we pick up nuances we couldn't have possibly seen before.

VIII. Simplify your explanations and create analogies. Streamline your notes and explanation, further clarifying the topic until it seems obvious. Additionally, think of analogies that feel intuitive.

- A. Every field of study has its own specialised terms. While it may be important to know them, it's also important to not confuse knowing jargon with knowing concepts. The Feynman Technique involves simplifying our initial explanations and refining our understanding through simple analogies..Why this step works:
- B. Simplicity is a proxy for understanding. It's easy enough to commit terms to memory, and repeat them back when prompted. But memorisation is not understanding. When we can't rely on big words that make us sound smart, we have to distill what we truly know to the most basic form. This is where true understanding takes place.
- C. Analogies are easier to recall and explain. When you understand a challenging concept, analogies allow you to create a short-hand for recalling it quickly and explaining it to others clearly. Learning material often provides ready-made analogies for us. For example, we all probably have "the mitochondria are the powerhouse of the cell" burned into our collective memories. However, pushing ourselves to create our own analogies is even more powerful than regurgitating a borrowed one that we may not actually understand.

IX. Organize and Review

- A. To test your understanding in the real world, run it by someone else. How effective was your explanation? What questions did they ask? What parts did they get confused about?
- B. When you're happy with your understanding, take the page you created with a simple explanation and put it into a binder. Following this technique for everything you learn gives you a binder full of learning that you can review a couple of times a year.

Trust the Quiz-and-Recall Method

Whether it's philosophy or calculus, the most effective way to imprint a concept is to first review it and then try to explain it, unaided, in your own words. If you can close your eyes and articulate an argument from scratch, or stare at a blank sheet of paper and reproduce a solution without a mistake, then you have fully imprinted that concept. It's not going anywhere. The same is not true if you merely read over something. Passively reviewing a concept is not the same as actively producing it. Most students make the mistake of relying only on passive review; they read and reread their notes and assignments, and assume that the more they read, the more they will remember. But as Ryan from Dartmouth warns: "Simply reading it over doesn't work. You have to make the extra effort to get it into your head."

Using the Quiz-and-Recall Method for Nontechnical Courses

To apply the quiz-and-recall method to nontechnical course material, you first need to construct a practice quiz for each chapter in your study guide. Fortunately, the questions for these quizzes already exist, since, if you've followed the advice of Steps #1 and #2, all of your notes should be in a question/evidence/conclusion format.

Therefore, the quiz for any given chapter can simply contain all of the questions from the notes you took for that chapter. You can be flexible here. If your notes contain some really broad questions—for example, an entire lecture that deals with only one idea—break them up into several smaller questions that, together, cover all of the relevant points. On the other hand, if your notes have a bunch of really small questions, you can combine some into larger questions to save space and time. This process is not an exact science; your goal is simply to produce practice quizzes that cover all the material contained in each corresponding chapter. If you can answer all the questions, then you understand all the big ideas. Once you've built your practice quizzes, go through them one by one. For each question, try to articulate the matching conclusion and provide some highlights from the supporting evidence. You don't have to reproduce the material in your notes word for word, but you do need a reasonable summary of the big idea and its support. Here's the important part: Don't do this only in your head! If you're in a private location, say your answers out loud using complete sentences.

However, if you are forced to review with other people around and you need to be quiet, then you can write out your answers. “The physical act of writing and the manipulation of the material in my mind was usually enough to keep things straight,” explains Melanie, a straight-A Dartmouth student. You don’t have to format these responses perfectly with correct spelling and grammar, but they must contain all of the pertinent information. No shortcuts. If you don’t say or write it, don’t consider it fully reviewed. Next, put little check marks on your quizzes next to any questions that you had trouble answering. Glance through your study guide to remind yourself of the right answers to these questions. Take a quick break.

Now, repeat the first step, except this time you need to answer only the questions that you marked during your first run-through. Put a new check mark next to the questions that you still have trouble with. Once again, look through your notes to get the right answers, and then take a quick break. Then go back to the practice quiz and try to answer the questions that you marked on your second run-through. You get the idea. Repeat this pattern until you complete a run-through without adding any new check marks. At this point, you’re done!

Using the Quiz-and-Recall Method for Technical Courses

The quiz-and-recall method is easily applied to technical courses. You already constructed your mega-problem sets; now you simply need to solve them. Start with the technical explanation questions—thinking about the general concepts first will make it easier to solve the specific sample problems that follow. As with nontechnical courses, try to provide an articulate answer for each problem, and if possible, give your explanation out loud, as if lecturing to a class. Otherwise, write out your answers clearly. Don't skip any important details. Once you're done with the technical explanation questions, move on to the sample problems. Try to answer each. Again, don't do this in your head. "I don't just read the material," explains Worasom, a straight-A student from Brown. "I write the important equations and concepts out by hand." Your solutions don't need to be as detailed as if this was a real assignment, but they should clearly demonstrate that you know what you're doing. If you can't explain exactly how you got from the question to the answer, then you don't yet understand this problem. Be honest with yourself: If you're just regurgitating memorized solutions, you aren't prepared to handle new questions on a test.

Memorize over Time

If you have material that must be truly memorized— dates, artists, chronologies, formulas—there are, unfortunately, no real shortcuts. You just have to keep working with your flash cards until you have no trouble providing the right answer, even after you shuffle the cards into a random order.

Memorization is particularly dependent on your available mental energy. It doesn't work if you try to commit items to memory for eight hours straight, but it does work if you memorize only an hour at a time and only one or two hours a day. So separate the task of memorizing from your other review. Spread the work out over many days, and never dedicate too much time to any one sitting with your flash cards. Melanie from Dartmouth recalls how some of her peers would "review their flash cards at any opportunity—eating dinner, waiting in line at an e-mail terminal," which is the most effective way to get through this tedious task and commit the necessary items to memory.

Step 5 Invest in “Academic Disaster Insurance”

Straight-A students have a knack for avoiding rogue questions. It's as if they invest in some sort of academic disaster insurance: protection against the unexpected return of those obscure topics that slip by when you doze off for a moment in class. In reality, this insurance policy is nothing more than a simple strategy: Eliminate your question marks. This technique can be employed throughout the term and, over time, significantly reduce the chance that you will be baffled by an unexpected exam question.

Eliminate Your Question Marks

In Step #1, we covered smart techniques for taking notes in class. If you remember, this strategy suggests that you put a question mark in your notes for any topic that flies by without you really understanding the conclusion. This will occur occasionally in both technical and nontechnical courses—sometimes as the result of your attention wandering and sometimes as the result of the professor heading off on a tangent and not offering a satisfactory explanation.

These question marks are dangerous. As Christine from Harvard puts it, by skipping a point made in a lecture, “you’re gambling with the possibility of being truly in the dark on the exam.” The scenario is simple. During the semester a few topics slip past your attention in class, so you end up with a handful of question marks in your notes. When it comes time to study, you have more than enough big ideas that you do understand, and that you need to review, so the occasional question-marked topic gets ignored. You enter the exam feeling prepared, and then, as luck would have it, you find yourself face-to-face with a big essay question covering one of those bypassed concepts. Whoops. To prevent this from happening, you need to eliminate these question marks. The key is to start this process well before the exam. If you leave all of these question marks unanswered until you start studying, you will end up spending many extra hours looking up the required explanations. Learning a large quantity of material from scratch during the review process is a mistake made by average students—and you should avoid this. Instead, try to knock off question marks as soon as they arrive. By the time you begin studying you should, as

Robert, a straight-A student from Brown, explains, “have at least a vague understanding of every topic that will be covered on the exam.” The following four tactics, if used regularly, will help you achieve this goal. They provide a solid defense against unclear ideas and will allow you to start the study process with an explanation in mind for all relevant topics.

- Ask questions during class. “When in doubt, I just ask questions in class for more clarification,” explains Worasom from Brown. If a topic slides by you, raise your hand and ask for a clarification. The more question marks you eliminate on the spot, the less work you will have to do later.
- Develop the habit of talking to your professor briefly after class. “Talk to the professor after class, or send him an email asking for clarification about questions that arose during his lecture,” suggests Jason from Penn. There is nothing unusual about this. Most professors will stick around for five or ten minutes after the bell to answer final questions. Take advantage of this time. When the class ends, head over to the professor and see how many of the question marks of the day you can get eliminated. You should then immediately correct your notes before you forget the explanations. Will this turn you into a brown noser? No! The brown nosers are those who come up to the professor only to tell him what parts of the lecture they found interesting, or to offer up some of their own “brilliant” thoughts on the topic. You, on the other hand, have a list of focused questions that you want answered, which makes you seem smart, not snivelling.
- Ask classmates. If you’re still unclear, James, a straight-A student from Dartmouth, recommends that you “talk with other people about the topic.” Send an e-mail or corner them in the hall soon after the lecture. If they understand the topic, it will take them only a few minutes to explain it to you while it’s still fresh in their minds.
- Come prepared to exam review sessions (if offered). Many classes offer a formal review session the week before the exam. Go to these. Before you arrive, jot down all of the topics from your notes that you are still unsure about. Then, during the session, try to get all of them answered. Don’t be worried about having a lot to discuss. More often than not, review sessions suffer from too few student questions, so your professor or TA will appreciate your preparation.

The goal of these defensive tactics is to eliminate your question marks without adding any study time. If, however, despite your best attempts, some of these unclear topics persist until your review, your last-ditch defense is to skim. You probably won’t have time at this

defense is to skim. You probably won't have time at this point to look up detailed explanations from scratch for every leftover question mark. And, even if you did, the effort would be way too time consuming (remember: Straight-A students avoid long study hours), so skim over just enough material to have something to say for each of these points. On the off chance that one of these lingering question-marked topics comes up on the exam, at least you won't leave a blank page. But this situation can still be dangerous, so follow the first four strategies to reduce the topics you don't understand as much as possible before your studying begins.

Step 6 Provide “A+” Answers

Even the most prepared student can bomb an exam due to poor test taking skills. The potential pitfalls during an exam are numerous, but the most common are: (1) running out of time and (2) providing answers that, although detailed, don't fully answer all parts of the question being asked. In fact, these two dangers work together in a devilish counterbalance, making them particularly hard to conquer. That is, if you try to avoid spending too much time on questions, then you are likely to provide time on questions, then you are likely to provide

incomplete answers. On the other hand, if you try to provide detailed answers, then you are likely to run out of time.

The situation sounds dire, but it's not. With the right strategy, you can eliminate these fears and ensure that your grade properly reflects your level of preparation. Straight-A students recognize this point, and when asked about test-taking, they provided detailed responses, proving that for them, this final step is no mere afterthought. They treat the test-taking process with great respect, and this attention is reflected in their consistently high grades. Their advice has been culled into five key strategies. Together, they provide a comprehensive test-taking system, finely tuned through experience to maximize performance. Follow these rules on every exam, and you'll be able to transform yourself into a test-taking machine—cool, confident, and ruthlessly efficient as you move from question to question, providing the best possible answers.

Strategy #1: Review First, Answer Questions Later

“I always read through the entire exam first,” explains Robert from Brown. This is good advice—for any exam, your first step should always be to review all of the questions. If it’s an essay exam or a technical exam with a relatively small number of questions, then read each prompt carefully. If the exam is multiple choice or contains many questions, skim through quickly and get a feel for which topics are covered. This review familiarizes you with the length and relative difficulty of what lies ahead. It also primes your brain for the topics you’ll need to address. “Always scan all the questions,” explains Anna from Dartmouth. “This allows your mind to think about all of them, even while you are focusing on one in particular.” In other words, while you toil away on an early question, another part of your brain, working in the background, will begin to retrieve information relating to the topics still to come. This actually happens, and it helps you answer the later questions more quickly.

Finally, and perhaps most significantly, this first step also helps you relax. Stress proliferates in a classroom right before an exam is distributed. It’s a make-or-break situation. Months of effort have led up to this single moment, and you have only a scant hour or two to prove what you know and secure your final grade. You begin to question yourself. Did you study everything you needed to? Have you forgotten important ideas? What if the to? Have you forgotten important ideas? What if the exam focuses on a subject you know nothing about? If you left it blank, what would happen then? Just thinking about this situation is enough to make most undergrads sweat.

However, by taking the first few minutes to carefully review the exam, you break this mounting tension. It gives you something productive to do that doesn’t involve actually answering questions. Once you complete this task and build a better idea of what to expect, the exam becomes less menacing. You’ve seen the questions, and (hopefully) none seem impossible. You begin to say to yourself: Okay, maybe this isn’t all that bad. Your confidence rises, your heart rate lowers, and your stress begins to dissipate. Now you can turn your full attention to providing standout responses.

Strategy #2: Build a Time Budget

At any given point during an exam, you should know the maximum number of minutes you have to spend on the current question before moving on to the next. As Doris from Harvard puts it: “I lay down very strict time limits for myself on each question.” This strategy goes a long way toward avoiding time trouble; it keeps your attention focused and prevents you from spending too much time on any particular question. The key to maintaining this keen awareness is to build a time budget. First, take the time allotted for the exam and subtract ten minutes. Next, divide this amount by the number of questions. The result is how long you have to spend on each prompt.

What should you do with this information? For an exam with a small number of questions, mark right on the test pages the time when you should begin and finish each one. For an exam with many questions, divide the exam into equal fourths, then jot down the time you should begin and end each section. In both cases, these recorded times will keep you updated on how close your current progress matches your predetermined schedule. Why do we subtract ten minutes in the first step? This provides a safety buffer. You want a few extra minutes available here and there to be able to double check your answers when you are finished, or go back and add more insights to questions on which you were rushed

Strategy #3: Proceed from Easy to Hard

Straight-A students almost never answer exam questions in the order that they are presented. Years of informal experimentation by successful students have demonstrated that the most effective way to tackle an exam is to answer the easiest questions first, and this is exactly what you should do. Start with the most approachable questions before moving on to the more forbidding. Don't worry if this has you skipping around all over the exam—in most cases the provided order is irrelevant. The advantage of this approach is that it first focuses your energy on the questions you know the most about, ensuring that you get maximum points on these. It also gives you a better chance of conquering the more difficult ones. “I always skip a question if it does not come to me immediately,” explains Ryan from Dartmouth. “This keeps my mind clear to answer other questions and hopefully something will jog my memory.” When you come across something hard early on in the exam, your natural instinct is to panic. You have so many more questions to finish, and you can almost feel the minutes ticking away as you stare blankly at this one particular

roadblock. It can be tough to get your focus back to wring out as many points as possible from the easier questions that follow. If, instead, you tackle this same roadblock at the end of the exam, you'll find that the situation seems less dire. You've answered everything else, so all that's left to do is working out this final puzzler. More often than not, you will find the mental block diminished. Without the pressure of other questions looming in the background, you can take a more relaxed approach. You might not know the best answer, but you can spend some time to devise a reasonable answer. Because you have nothing else left to finish, you can spend the remainder of the time polishing this answer, thinking, and repolishing. The result is the strongest possible outcome given your state of preparation.

Strategy #4: Outline Essays

When facing an essay question, don't just start writing and see what happens. This approach leads to rambling answers and missed concepts. Instead, your first step should be to jot down a quick outline. This might seem like a waste of time, but in truth it can be invaluable.

First, reread the question carefully. As Matthew from Brown explains: "Usually, you can isolate three or four mini-questions from a single essay question." Underline each of these mini-questions; this will help you flesh out your outline and avoid an incomplete answer. "Then, outline on paper (not in your head) the way that you will use what you know to answer these mini-questions," continues Matthew. To do so, use the margin of the exam to jot down all of the points you can recall that are relevant to the question. Record only a few key words for each point to save time and space. For example, if you want to mention an argument made by an author named Robert Caro dealing with Lyndon Johnson's views on race relations, you might jot down: "Caro—race." Next, go back and check the question parts you underlined in the first step. Make sure each is adequately addressed by the points you just noted in the margin. When you're sure that you have identified all the relevant information for the essay, number these points in the order that you want to present them. Only now should you begin writing your essay. Follow your outline, and the writing will proceed smoothly. You should be able to quickly produce a solid response that draws on everything you reviewed and addresses all parts of the question asked.

Strategy #5: Check Your Work

Advice and go back and check your work. You will be surprised by how many times this final review turns up a mistake in a technical problem or an important concept that you forgot to mention in an essay. If, after your first round of review, you still have time left over, then go through and check again. If there is a problem you feel particularly shaky on, use this time to go over it in detail, augmenting the answer wherever appropriate. Don't worry about using carets and arrows to add in new phrases and facts to your essays, or to point out added steps in your technical problems. Neatness doesn't count on exams; it's the content that matters. It's tempting to relax after finishing your exam, perhaps walking proudly to the front of the classroom and handing it in before anyone else. But aside from the wistful stares of your classmates, this strategy is ill conceived. Double checking your work up to the last minute can make the difference between an above-average student and an academic star.

Part Two Cheat Sheet

Step #1. Take Smart Notes

- Always go to class and try to take the best notes possible.
- For nontechnical courses, capture the big ideas by taking notes in the question evidence/conclusion format.
- For technical courses, record as many sample problems and answers as possible.

Step #2. Demote Your Assignments

- Work a little bit each day on your assignments; avoid suffering from day-before syndrome.
- Read only the favored sources on the syllabus in detail. To decide how much time to spend on supplemental sources, remember the importance hierarchy: – readings that make an argument are more important than – readings that describe an event or person, which are more important than – readings that only provide context (i.e., speech transcripts, press clippings).
- Take reading notes in the question/evidence/conclusion format.
- Work in groups on problem sets, solve problems on the go, and write up your answers formally the first time.

Step #3. Marshal Your Resources

- Figure out exactly what the test will cover.
- Cluster your notes for nontechnical courses.
- Build mega-problem sets for technical courses.

Step #4. Conquer the Material

- Embrace the quiz-and-recall method. It's the single most efficient way to study.
- Spread out memorization over several days. Your mind can do only so much at a time.

Step #5. Invest in “Academic Disaster Insurance”

- Eliminate the question marks for topics covered in class or from the reading that you don't understand.

Step #6. Provide “A+” Answers

- Look over the whole test first.
- Figure out how much time you have to spend on each question (leaving a ten-minute cushion at the end).
- Answer the questions in order of increasing difficulty.
- Write out a mini-outline before tackling an essay question.
- Use any and all leftover time to check and recheck your work.

Essay and Papers

Paper writing is hard, but the good news is that it doesn't have to be as hard as most students make it. Let's begin by taking a closer look at the paper-writing process itself, which can be broken down into three separate components:

1. Sifting through existing arguments.
2. Forming your own argument.
3. Communicating your argument clearly.

The sooner you dispel the notion that writing is the most important part of paper writing, the easier it will become for you to reap the benefits of the straight-A approach.

Research Papers vs. Critical Analysis

Essays

Writing assignments come in many varieties. Some require a lot of original research, whereas others require only a critical discussion of a topic introduced in class. Some have ulcer-inducing length requirements, whereas others ask for only a handful of pages. We capture these differences with the simple classification scheme of research papers versus critical analysis essays. Some assignments, of course, may fall outside of these two descriptions, but, for the most part, they capture the major variations in paper writing. All of the advice that follows explicitly describes which of these two types it applies to.

Research Papers

A research paper requires you to choose a topic within provided parameters and then devise an original thesis relevant to your chosen topic. For example, the broad parameters for your topic choice might be “anything involving the British Empire,” the specific topic you choose from within these parameters might be “public schools and the British Empire,” and the thesis you choose might be “the public school system in nineteenth-century England had a curriculum specifically tailored to the requirements of the British Empire.”

Research papers require original research to support your original thesis, and, accordingly, their page lengths are long and their due dates are generally a ways off from when they are assigned. If you spread out the work appropriately and choose the right topic, research papers can provide a rewarding intellectual challenge. Proposing and supporting an original argument is exciting. However, if left until the last minute, these assignments can become a nightmare. More than a few students have suffered a nervous breakdown from the stress of tackling a major research paper at the last moment. So for these assignments in particular, take careful note of the scheduling recommendations that follow.

Critical Analysis Essays

Critical analysis essays are the bread and butter of most liberal arts classes. These essays are short, and they typically require you to analyze one or more of your class reading assignments. They are often set up as a comparison, for example: “How do Nordlinger and Hopkins differ in their approach to understanding American Isolationism. What cultural and theological sources account for these differences?” Critical analysis essays differ from research papers in several significant ways: Topics are provided in advance, your thesis is nothing more than a specific answer to the question asked in the assignment, and there is little-to-no original research required. Not surprisingly, these essays require less time to complete than research papers. Their goal is to test your understanding of the material presented in class, not to seek out and present new ideas. Don’t get the wrong idea—these essays are not necessarily easier than research papers. College writing assignments follow a simple rule: The required precision of your thinking works in direct proportion to the constraint of the material. That is, the more specific the assignment, the more subtle and detailed your thinking must be. So beware. If your assignment covers only one chapter, then you’re going to need to understand every word of that chapter and be able to articulate your analysis with precision.

Step 1 Target a Titillating Topic

Remember: A topic does not equal a thesis. A topic describes an interesting subject or area of observation. A thesis presents an interesting, specific argument about that subject or observation. Let's look at some examples. As mentioned, for a critical analysis essay, the topic is provided, so this step won't be applicable. For a research paper, however, you get to choose the topic—so we'll focus on the specific case of research paper topic selection for the remainder of this section.

Choosing a Research Paper Topic

Typically, the professor will provide some loose parameters. For an art history course, these might be: parameters. For an art history course, these might be: "Any artist covered in the class so far." For a political science class they might be: "Economic policy and Latin America." The key is to choose a topic, within the constraints of the assignment, that excites you. All work that follows on your paper will stem from this topic; if you are not intrigued by the idea, then the paper-writing process will be tedious. If, on the other hand, you are fascinated, or at least curious, then the process will be that much easier. The best way to identify a titillating topic is to start looking for one early. "I work on topic ideas in my head and on scraps of paper beginning anywhere from a week to a month in advance of the actual deadline for a paper," explains Doris, a straight-A Harvard student. Follow this approach. On the very first day of class, read the description of the research paper(s) that will be assigned. The syllabus should describe each paper's topic parameters, and the professor will usually discuss these assignments briefly early on in the term. Once you know the parameters for the paper, you should constantly be on the lookout for a particular subject or observation that interests you. If one reading assignment really grabs your attention, jot down the topic so you'll remember it later. If a professor poses an interesting question during class, or piques your curiosity by describing a compelling open area of research, make a note of it. As Sean, a straight-A student from Yale, explains: "Keep an eye out for concepts that interest you in the readings and lectures. If there's something that grabs you, it will probably make a good topic." If you have trouble finding a topic in advance, you have two options. First, as Chien Wen, a straight-A student from Dartmouth, advises: "Approach your professor with some ideas you have and let him recommend some appropriate readings." Professors know their field well, so they should have no trouble pointing you toward some resources to help flesh out your initial thoughts. Second,

as Chien Wen also advises: “Read your primary sources carefully.” Grab a textbook or similar general source from the class, and then skim through and look for angles that catch your attention, passages that make you ask “why,” or descriptions of competing arguments debating an interesting subject. “Be imaginative and intuitive—look for unusual connections between individuals, ideas, and broader themes,” says Chien Wen. In general, the more care you take during this first step, the easier the rest of the paper-writing process will be, so take your topic choice seriously.

Step 2 Conduct a Thesis- Hunting Expedition

You need to construct a thesis that makes a compelling argument concerning this topic. Once again, for a critical analysis essay, most of the work toward constructing your thesis has already been done for you. Typically, the essay prompt will contain a specific question (i.e., “How do the two arguments differ?” or “Why does the author say this?”), and your thesis is a summary of your answer. For a research paper, on the other hand, you might be dealing with a very broad topic that requires significant digging to find an interesting and supportable idea that can be expanded to fit the required page limit. In both cases, some initial research is required. A thesis devised from scratch is dangerous. Without some initial exploration, you have no idea whether or not your idea is viable, and there are few experiences worse than being forced to restart a paper after many hours of work. At the same time, however, you don’t want to dedicate days to intensively reading every book in the field in search of a perfect thesis, because this would be inefficient. For a critical analysis essay, the solution is simple: Review both the reading notes and lecture notes that relate to the essay prompt. And that’s it! This should provide a rough idea of how you are going to answer the question posed by the assignment. Therefore, your thesis has been found. Even though it’s simple, don’t skip this step for critical analysis essays. The earlier you develop an idea of what you are going to say, the more time you have to refine the nuances of your argument. For research papers, on the other hand, the task of finding a thesis is more complicated. No sources have been preselected for you, and no specific question has been provided. All you have is a general topic that you thought up yourself. Now you must wade into a vast sea of knowledge and somehow find enough material to devise a strong thesis—while avoiding drowning in the sheer volume of available information. Not surprisingly, the straight-A students interviewed for this book have mastered the art of conducting research paper thesis-hunting expeditions. Their goals are twofold: (1) find an interesting thesis that can be supported within the scope of the assignment; and (2) minimize the time required to conduct this search. Accomplishing both of these goals sounds hard, but straight-A students get it done. What’s their secret? One simple phrase: Start general, then move one layer deep. Let’s take a closer look at what this really means. Start General, Then Move One Layer Deep “I usually begin with basic sources,” explains Chris, a straight-A student from Dartmouth. “If I’m doing a paper on the Kurds in Turkey, for example, I get a recently published general history on this topic.” Similarly, if your topic is Faulkner’s early writing, you might find one or two Faulkner biographies and then focus only on the chapters dealing with his early years. If you have a

hard time finding a few general sources for your topic, then ask your professor—he'll have plenty of titles to recommend. In addition, keep in mind that most courses set up a reserve shelf at the campus library. This shelf contains books that were selected by the professor because of their relevance to the course. Typically, you can check out reserve books for only a couple of hours at a time, so they should always be available to the students who need them. This is a great place to find general sources. So that's step one (the "start general" part of the strategy). The reason we need a second step is because you shouldn't expect to find your thesis idea in a general source. Of course, you might get lucky and find an interesting thesis during this first step. In general, however, overview sources will be much too broad to reveal a targeted and interesting argument that hasn't already been written about extensively. The main reason you found these general sources is to get at their bibliographies. As Chris goes on to explain: "I read any chapters from my general sources that look useful for my paper. I then look up the sources used in that chapter." In other words, the second step of your thesis-hunting expedition is to examine the list of books and articles cited in the relevant sections of your general sources. From this list, choose the cited works that look the most promising, and then go find them in the library. These sources will be more focused—perhaps journal articles or books addressing only a small number of specific arguments. You are most likely to come across an interesting and appropriately targeted thesis idea using these more focused sources. Let's apply this approach to our Faulkner example from before. Perhaps one of our general sources cites a journal article on the influence of a specific European modernist writer on Faulkner. You find this journal article, and while reviewing it you notice that it mentions, in passing, a list of other modernist writers who might have had a similar influence. Aha! Now this could be an interesting thesis. You might choose one of these modernists from the list and then look for historical evidence of their connection to the primary writer. Perhaps, instead, one of the general sources talks about a period of Faulkner's life that he spent in Europe. Maybe it also mentions that our only records of this travel are letters written by the young author himself, and then it provides a citation to a collection of these letters. You then locate these letters, begin to read through them, and notice that he mentions a particular bar in London several times. This too might be a source of a fascinating thesis. You could investigate the intellectual climate of London nightspots of the time and posit their potential influence on Faulkner's work. From there, perhaps the core of your paper could be to present a piece of writing from right before the trip, and another from right after, and then argue which stylistic changes may have been influenced by his foray into the intellectual intensity of the London literary milieu. The key is to keep in mind that even very small observations can

lead to large, interesting discussions. How do you know your thesis idea is good enough to support an insightful paper? “A great thesis typically has at least these four qualities,” explains Christine, a straight-A student from Harvard. “It’s provocative, nuanced, direct, and inclusive.” She goes on to warn: “A thesis should, at the same time, also show a grasp of the complexities of a subject—‘in this poem, X symbolizes Y because Z’ is a weak type of thesis structure, far too reductive and simplistic—don’t be afraid to leave room for ambiguity and unresolved issues.” Wendy, a straight-A student from Amherst, puts it simply: “The most important part of your paper is the thesis. Once you have a solid thesis, the rest just falls into place.” Here’s the tricky part: Your thesis will change and evolve as you continue the paper-writing process. This is inevitable, because you haven’t done your exhaustive research yet. At this early stage, your thesis more likely explains the type of connection or answer you hope to find, rather than the final connections and answers themselves. To revisit our Faulkner example, your early research may indicate that the social milieu of a certain London nightspot influenced a young Faulkner, but you might not yet know all the ways this influence was manifest. More research is required, and that’s okay. You should embrace this evolution of your ideas as the process continues. For now, it’s sufficient that your fledgling thesis looks like it’s on the path toward fulfilling the properties mentioned above. In other words, before continuing, make sure that your preliminary research strongly indicates that something similar to your thesis idea will be supported by the more detailed investigations to follow. Be honest with yourself: If you made up your thesis simply because it sounded cool, but have no real reason to believe it to be true, then you’re courting a paper-writing disaster. If, on the other hand, several pieces of early evidence point to the types of interesting connections described by your thesis, then you’re on the right track.

Step 3 Seek a Second Opinion

At this point you should have an interesting topic and a targeted thesis. You're well on your way toward a standout paper, but don't get too far ahead of yourself. It's time to take a step back. More than a few students have dived deep into the paper-writing process, supported by what they thought was a compelling thesis, only to find out many pages later that their premise was not as strong as it initially seemed. Perhaps they fail to find enough evidence to support the argument. Perhaps they stumble across another source that has already made the exact same point. Or, as is often the case, perhaps they find their thesis to be too broad to be succinctly argued within the scope of a paper assignment. The thesis-hunting tips of the last step help eliminate this possibility, but they're not enough by themselves. Once you think you have a good thesis, a final step remains before diving fully into the research and writing process. As Rielle, a straight-A student from Brown, explains: "I often talk to a professor to clarify my ideas before I begin writing." This is great advice. For every research paper and significant critical analysis essay (i.e., assignments more than just a few pages long), you should make a habit of discussing your targeted thesis idea with your professor. Go to office hours, or make an appointment, explain your topic and thesis, then ask the following questions:

- 1. Is my idea appropriate for the assignment?*
- 2. Does it cover too much?*
- 3. Is it too simple?*

For a critical analysis essay, if the professor deems your thesis appropriate, this is a good sign that you are not going to get stuck. You can now move ahead with confidence. For a research paper, if the professor deems your thesis appropriate, take advantage of this time to explain some of the sources you plan to examine. The professor will likely have some additional sources to suggest. Write these down. This just saved you some suggest. Write these down. This just saved you some serious research time! For both types of papers, if the professor isn't enthusiastic about your thesis idea, then he or she will likely help you adjust it into something that is reasonable. When you leave this meeting, which should require only ten to twenty minutes, you will have confidence in the foundation of your paper. You can now move full speed into the research stage without fear of reaching a devastating dead end later on in the process. It's amazing how many students ignore this incredible resource. One simple meeting can make the difference between a standout work and an incoherent dud. Remember, this step is not intended as a shortcut. If

you skipped the previous step and show up at office hours without a targeted idea, the professor is not going to give you one for free. However, as Christine from Harvard explains: “They’ll rarely refuse to listen if they see you’ve thought things out in advance.”

Step 4 Research like a Machine

Not surprisingly, research is the domain of the research paper. For a critical analysis essay, your sources are already specified, and there are probably only one or two of them. Therefore, when working on an essay, you can skip this step and move on to Step #5 (Craft a Powerful Story), which describes how to organize your argument. For research papers, however, the following advice is crucial. Why? Because how you research can make or break your paper-writing efforts. If your strategy is haphazard—as is the case with most students—then two immediate problems will arise. First, the writing process will become frustrating and tedious, since you will be forced to continually stop and seek out new sources to extend your argument. Second, and more important, the resulting paper will be weak. A good argument requires a solid grasp of all relevant information. You want all the necessary facts and ideas to be at your fingertips, easily manipulated, sourced, and shuffled, as you build your case. If your sources are incomplete and disorganized, then your paper will be, too. On the other hand, you can also run the risk of spending too much time on research. Many eager students have succumbed to the horrors of research recursion syndrome—an unhealthy need to go find “just one more source,” often leading to hours and hours of wasted time, dorm rooms overwhelmed with teetering stacks of books, and one seriously sleep-deprived student. This is grind territory, and you should avoid it at all costs. So while at first glance it may seem easier than choosing a thesis or writing the paper itself, in fact the research step of paper writing is easy to get wrong. Fortunately, straight-A students have figured out a way to walk the research tightrope—getting the information they need without becoming lost amid the endless available sources. Their strategy can be summarized by a simple phrase: Research like a machine. They follow a system—a mechanical process, the same for every paper—that produces consistent high-quality results. Feed them a thesis, watch their wheels turn, and then out pops a set of photocopied, organized, and annotated notes. Their system ensures that the quality of their research is sufficient to fuel a standout paper and at the same time requires the minimum amount of time to achieve this goal. Sounds pretty cool, right? But how does it work? Their system is based on these four steps:

1. *Find sources.*
2. *Make personal copies of all sources.*
3. *Annotate the material.*
4. *Decide if you're done. (If the answer is “no,” then loop back to #1.)*

That's it. The devil, of course, is in the details. So let's take a closer look at what each of the steps entails.

1. Find Sources

There are two types of sources: general and specific. As described in Step #2, the former include overviews of your topic (i.e., biography or textbook), whereas the latter focus on specific arguments (i.e., a journal article or book about a specific event or idea). For a college-level paper, most of your best information is going to come from specific sources. The hard part, of course, is finding them.

Step #2: Start with general sources and then look in their bibliographies for more targeted resources.

As David, a straight-A student from Dartmouth, says: "Once you have two or three materials that you like, it's all about the bibliographies...find out where the author found the fuel for his arguments and go check those out." In Step #2, I suggested that you ask your professor or browse the course reserve shelf to find some of these general sources. Another place to look is your library's online card catalog. This sounds obvious, but using an online catalog correctly is not a trivial task. Just typing in keywords might not turn up every book that deals with your topic of interest. You need some more advanced tricks. One such trick is to take advantage of the Library of Congress (LOC) topic classifications. What are these? The Library of Congress tries to classify all books into one large hierarchy of topics. For example, Heinrich Harrer's fascinating book *The White Spider* (an account of the first team to ascend the infamous North Face of the Eiger Mountain) is described by the following two classifications:

1. Mountaineering—Switzerland—Eiger—History

2. Eiger (Switzerland)—Description and travel

When you find a book in an online card catalog, its corresponding LOC topic classifications should be listed. The cool part is that these topics should also be hyperlinked. That is, if you found an entry for *The White Spider*, you could click on Mountaineering—Switzerland—Eiger—History to return a list of every book in the library under this classification. Therefore, if you find one general source on a topic, then you can easily find many others. And once you have found general sources, you can turn to their bibliographies to find something more specific.

The second strategy for finding specific sources is to search for them directly. This approach is important. Not every specific source relevant to your thesis can be found in the bibliography of a general source. This is particularly true for more recent scholarship. Books take a long time to write; if a paper was published only within the last few years, it is

probably too soon to find a general tome that cites it. The problem here is that specific sources can be difficult to find. For example, continuing with the Eiger topic introduced above, let's say your thesis within this topic is: "The many failed attempts to ascend the North Face of the Eiger played an important role in the development of Swiss cultural identity during the first half of the twentieth century." Finding a general source about the Eiger, such as *The White Spider*, is easy enough. But finding a targeted source on the impact of the Eiger on Swiss cultural identity will be significantly more complicated. Simply typing "the impact of the Eiger on Swiss cultural identity" into the library card catalog probably won't turn up many hits. So how do you locate these elusive specific sources? There are four main search tactics.

Search Tactic #1: Break Up Your

Query into General Chunks If you can reduce your specific query to a group of related, yet succinct, general searches, you will have a much better chance of finding a relevant source. Following the Eiger example, you might try:

- Alpine hiking Switzerland culture
- Switzerland cultural identity
- Alpine hiking
- Mountaineering Switzerland

Any one of these more general queries could turn up a source that either directly references your thesis or makes a point that supports your thesis. With practice, you will get better at constructing these general probes aimed at illuminating a specific idea.

Search Tactic #2: Use Journal Databases

As mentioned, specific sources are more likely to be scholarly articles than books. Your library card catalog does not index articles. Therefore, as Chris from Dartmouth recommends, you should consider "article database searches (like JSTOR) on the specific topic." How do you find these databases? Your library Web site should contain a list of available electronic resources. At some point during your freshman year, you will probably be given an orientation on this topic. (Even if you sleep through it, as most of us do, it shouldn't be that hard to figure out.) This list of resources is usually broken up by academic concentration (i.e., Political Science, Anthropology, and so forth). Go to the concentration relevant to your paper, and you should see a list of searchable archives. Many of these resources will be databases of scholarly articles, so search these focused

databases using the general search term chunks described in the preceding tactic and see what pops up. If your topic is interdisciplinary, meaning that it draws from multiple academic concentrations, follow Chris's advice and try a big database like JSTOR (<http://www.jstor.org>), which contains scholarly articles on a large variety of academic topics.

Search Tactic #3: When in Doubt, Google

"Google is your friend, first and foremost," says David from Dartmouth. This is good advice—as Google is a great tool—but it should be used with some caution. A good rule of thumb is: Don't cite Web sites. Academics don't trust them. Journal articles go through extensive peer-reviewing before they are published, and academic books are written by experts and rigorously edited. On Web sites, however, anything goes. Therefore, they're worthless in terms of supporting an argument. Referencing Web sites is something you do in high school. If you do this in college, be prepared to experience the wrath of your professor. This being said, Google is still immensely useful. Not for finding Web sites to cite, but for finding Web sites that reference books and articles relevant to your thesis. For example, a search for "Eiger and Swiss Cultural Identity" might actually turn up some Web sites dealing with, or related to, this obscure issue. The Google search algorithm is a lot smarter than the one used by card catalogs, so even very complicated queries can turn up surprisingly accurate results. If you're lucky, some of these Web sites will mention specific sources—a book name or article title. Now you can look up these in your card catalog, and then treat them like any other formal source.

Search Tactic #4: Ask a Librarian

Most college libraries are staffed with reference librarians who want nothing more than to help you find the information that you seek. It's what they're paid to do, and they're great at it. Too many students, however, ignore this wonderful resource. Here you have experts who can save you hours of struggle by conducting advanced searches on your behalf; yet most students never think to take advantage of the opportunity. Making a visit to the reference desk should be one of your first steps when researching a challenging assignment. Simply explain your topic and thesis to the librarian, and he or she will walk you through several searches. Not only will this identify some specific sources that you may have otherwise missed, but it will also expose you to new library resources and databases that you can now use for future projects. The more time you spend with reference librarians, the better you will become at finding solid material on your own.

2. Make Personal Copies of All Sources

How you handle the sources makes a big difference in the overall efficiency of the paper-writing process. Though there are many ways to deal with the book chapters and articles relevant to your research efforts, many of the straight-A students interviewed for this book favored the following strategy: Make a photocopy or printout of all relevant material. If you find a book that has two chapters related to your topic, photocopy those two chapters. If you find an important journal article, photocopy the entire article. If you find an article online, or a relevant Web site, print it out. The goal is to create your own personal hard copy of all sources. The advantages of this approach are numerous. First, these hard copies are portable. It's easier to carry around a stack of photocopies than a stack of books and journals, so you can take your research with you to your secret study spots or office hours. Second, the information is more accessible. No flipping through big tomes or searching your computer hard drive; all the relevant information is stored in one condensed stack. You can now physically organize your sources, for example, by putting them into piles by author, clustering relevant arguments together with paper clips, or dividing them into folders labeled by subject. As Sean, a straight-A student from Yale, explains: "It's often easier to grasp something when you have a hard copy in front of you." Third, you can mark them up with impunity. "Printouts and Xeroxes of source info are often superior to books or digital copies," explains Christine from Harvard, "since you can annotate them to death." Feel free to underline things, highlight, draw arrows, cross out sections, or put big stars next to important points. In general, this approach maximizes the control you have over your information, ensuring that your sources work for you. However, there are a couple of important caveats to remember. First, make sure you label each photocopy with all of the information needed to later construct a formal citation. For example, if you photocopy a book chapter, jot down on the first page the name of the book, the author(s), the publisher and its location, and the copyright date. Or, if you prefer, follow Christine's advice and simply "make a photocopy of the title and copyright info" as found in the front of the book, so you can use it later while constructing the works cited for your paper and ensure that you don't find yourself "running back to the library at the last moment for citation info." Second, photocopy each source's bibliography. This way, if you come across an interesting reference in one of your photocopies, you will have easy access to the full citation attached to the reference. For articles, the bibliography is almost always listed immediately following the article. For books using the endnote format, you might have to flip to the back to find the bibliography for a specific chapter.

3. Annotate the Material

Finding a source, of course, is just the first step. A stack of photocopied pages is worthless if you don't know what information it contains and how it might be useful to your paper. You need to review the sources and annotate them with a concise description of the important information, if any, that they contain. Be careful how you proceed here. Your first instinct might be to follow the advice described in Part Two about how to take notes on your reading assignments. Don't do this—it's overkill. For now, you should be content to follow the advice of David from Dartmouth, who recommends **that you “skim, skim, skim.”**

Use The Following:

- A. VERY VERY FAST Reading- Skimming. Pages 47-51.**
- B. VERY FAST READING- Entertainment.**
 - I. Method 1-Speed Reading. FAST Reading. Pages 59-64.**
- C. FAST READING: Methods for Basic Knowledge For Deep Work or Bible Study.**
 - I. Method 1-Survey, Question, Read, Recite, Record, Reflect (SQR4). Pages 66-67.**
 - II. Method 2-Use 80/20 Principle For Reading. Pages 68.**
 - III. Method 3-Preview, Question, Read, Summary,Test (PQRST). Page 69.**
 - IV. Method 4-Flip Through Pages and Analyse. Page 70.**
 - V. Method 5-Devotional Bible Study by Using Devotional Books. Pages 71-72.**
 - VI. Method 6-Devotional Bible Read. Pages 73-74.**

Specifically, read through the source quickly. Every time you pass by an important definition, idea, or opinion that seems relevant to your thesis, jot down (on your computer or by hand) the page number and a quick description. For example, if the author argues a particular point of interest, write only what this point is— there is no need to also copy down the evidence he uses to support it as you would for notes on a reading assignment. If the source is a book, then, as Anna from Dartmouth explains: “Pick out only the chapters that relate to the specific aspect of the topic that you are interested in...it is not necessary to read the entire book!” When you're finished, staple your annotations to your personal copy of the corresponding source. In general, proper source annotations should act as

concise pointers, containing just enough information to show you where the relevant arguments are hiding. In the next step, where you organize all of your gathered information into a coherent structure, these simple annotations turn out to be exactly what you need to quickly assess the importance of each source. Therefore, you will end up needing to carefully read only the passages that help your paper. You should not think of this step as adding work. As you will soon discover, these concise annotations are actually going to save you a significant amount of time.

4. Decide If You're Done

There is no simple answer to this question. While it would be nice to offer a perfect formula for how much research is enough, it is impossible—there are just too many variations to contend with. Some short papers might require dozens of sources, while some long tracts may focus entirely on a handful of original documents. What follows is a rough procedure that should aid your decision about whether or not you have gathered enough research. Remember, this is just an approximation. Always keep in mind the context of your specific assignment. However, this approach should help reduce the guesswork involved in completing this step.

The Research Termination Determination Procedure:

1. List the topics (specific questions, facts, or accounts from your research) that are crucial to support your thesis.
2. List the topics that might help you support your thesis.
3. If you have at least two good sources for each of the topics from #1, and have at least one good source for a majority of the topics from #2, then you're done. Otherwise, you need to keep researching.

The reason these criteria are just an approximation is because at this early stage you probably don't know exactly how your thesis argument will proceed, so you don't know exactly what information you need. This procedure simply helps you estimate as best you can. By separating out the crucial from the potentially helpful, you are less likely to get stuck hunting down an obscure piece of information that you could do without. This approach is advised by David from Dartmouth, who describes the following similar procedure for sorting his research sources: "I make three piles of my sources: very useful, potentially useful, and not useful." To draw from our previous example, if your thesis deals with the Eiger and Swiss cultural identity, you might construct

your list of “crucial” and “might help” topics as follows:

1. Topics that are crucial to support the thesis:

- Basic historical information concerning the Eiger (when it was discovered, when it was first climbed, and so forth)
- Arguments concerning Swiss cultural identity at the turn of the century

2. Topics that might be helpful in supporting the thesis:

- Memoirs of people who were involved in the first ascents of the mountain
- Press accounts from the time (both Swiss and non- Swiss)
- General discussions of the role of sports and national pride

If you have a hard time tracking down one of the topics from the second list, you would still be okay. If, on the other hand, you have a hard time tracking down either of the topics from the first list, then you need to keep looking. In the next step, where you actually begin to outline your paper, it's expected that you might need to return briefly to the research phase and find additional sources to fill in any holes. If you follow the procedure above, however, you will minimize the amount of secondary research that you are forced to conduct—thus saving yourself from more hours in the library.

Step 5 Craft a Powerful Story

This step is where the magic happens. It's the fun part of paper writing—the moment of intellectual eureka. You have already defined (and verified) a compelling thesis, and you have at your disposal a collection of well organized and annotated research material. Now it's time to stretch your mental muscles and pull these pieces together into a powerful story. As Anna from Dartmouth says: "In order to write a great paper, you really need to make connections that other people haven't made, and the only way to do that is to think." This is the step where such thinking occurs.

Formulate Your Argument

"You must have a vision of what the overall structure of your paper will be," explains Frank, a straight-A student from Brown. "Organization of thought can make a decently researched essay into a fine piece of academic work." Formulating a solid argument, however, cannot be reduced to a system; it is a mental exercise that requires critical thinking and creativity. At the college level, there is no set structure that allows you to fill in the blanks and automatically produce a smart paper. As mentioned in the opening to Part Three, the intro, body and conclusion nonsense introduced in high school won't do you any good here. It's too simplistic, and your professors will be expecting more. In general, a good college-level argument should accomplish the following:

- 1. Draw from previous work on the same topic to define the context for the discussion.**
- 2. Introduce a thesis and carefully spell out how it relates to existing work on similar issues.**
- 3. Support the thesis with careful reasoning and references to existing arguments, evidence, and primary sources.**
- 4. Introduce some final prognostications about extending the argument and its potential impact on the field as a whole.**

There is, however, no set order or format for presenting these general points. One paper might start by defining the context and then move on to the thesis. Another paper might start with the thesis, argue it, and then introduce the broader context at the end. Many papers might interweave all four points. There is no right answer here. And the hard truth is that the only way to get better at organizing and presenting your thoughts is through practice. So write a lot and read good arguments a lot. This is the best recipe for

developing your skills for this step. That being said, there are some general pointers about how to go about formulating your argument. These aren't rules for what to say; rather, they are tips for how to get your brain fired up and your creative juices flowing.

Tip #1: When it comes time to craft the storyline of your paper, put yourself in the right mind-set. Grab a copy of *Atlantic Monthly*, *The New Yorker*, *Harper's*, or any other publication that features well crafted discussions. Peruse some articles, and then go for a walk along a quiet path. Alternatively, as David from Dartmouth recommends: "Talk to friends —if they are good friends they will allow you to bounce ideas off of them and talk through your work." You can also cloister yourself in a dusty, wooden-shelved, overstuffed-armchair-filled corner of the library, or argue with your professor during office hours. Reread related articles and chapters from your course syllabus. Watch a PBS documentary. Do whatever it takes to get the reasoning portions of your mind inspired and curious.

Tip #2: At this point, grab your source material from the previous step. If your assignment is a critical analysis essay, this will consist of only a couple of books and your reading notes. If it's a research paper, you might have a large stack of photocopied chapters and articles. In either case, dive into this information, and start letting the relevant facts and arguments settle into your mind. This is where your annotations will point you toward what's interesting, and help you avoid the irrelevant.

Tip #3: Take a break. Do something else. Let the pieces float around in the background noise of your mind. "The first thing I do when I have a paper to write is take a nap," explains Laura, a straight-A student from Dartmouth. "I crawl into bed and just think...as long as I'm thinking about the subject when I fall asleep, I will dream about the material and usually come up with some sort of interesting idea." Similarly, start looking for any opportunity to do a little thinking about your argument. "I think about my paper when I go around completing my daily chores, when I walk to class or when I wait on line in the dining hall," explains Anna from Dartmouth. Use this downtime to slide the pieces of your argument around in your head and play with the structure a bit. Keep returning to your research material as needed to find more details and to increase your understanding. You need to

expose yourself to the source material again and again to fully internalize it. Only then can you really pull together the best possible argument.

Constructing an Outline

You need an outline to capture the argument you just spent so much time devising. Keep in mind, however, that all outlines are not created equal. In fact, there are two major outline-related mistakes made by students.
